Because Israel does not have a written constitution, the rules and regulations governing how the Knesset functions—and even its establishment—are laid down in Israel’s Basic Laws. According to “Basic Law: The Knesset,” article 4, elections for the Knesset are to be “general, country-wide, direct, equal, secret, and proportional” (Government of Israel 2004). Israel has universal suffrage for all citizens aged eighteen and over, and all citizens are eligible to vote in these elections. In this respect, elections for the Knesset are viewed as general elections, as opposed to elections for municipal officers. With respect to the elections being “country-wide,” for the purposes of
Knesset elections, the entire country is considered one district. There are not separate electoral districts based on geographic region for distribution of Knesset seats. Numerous parties participate in Israeli politics and are represented in the Knesset. According to the 1992 Parties Law, a party is defined as “a group of persons who joined together in order to promote in a legal way political or social objectives and to express them in the Knesset by their representatives.” Parties can be established by registering the signatures of one hundred adult Israeli citizens who are residents of Israel. However, a party is prohibited from registering or competing in the electoral-legislative process if one of the following four conditions is found to be present in its “objectives or actions”: (1) it rejects the existence of Israel as a Jewish and democratic state; (2) it encourages racism; (3) it supports the armed struggle against the State of Israel by either terrorist organizations or enemy states; and (4) it is believed that the party will be used “for illegal activities.”

In order to gain entry to the Knesset, a party must obtain 2 percent of the votes cast in the election. Since the entire country is one “district” for the purpose of Knesset elections, parties must receive 2 percent of all votes cast throughout the country in order to be represented in the Knesset. The division of seats in the Knesset is based on a system of proportional representation. The number of seats that each party receives in the chamber is proportional to the number of votes it receives in the election, once the 2 percent threshold has been passed. Previously, the threshold had been as low as 1 or 1.5 percent, but it was raised to 2 percent in 2003. Individuals are elected to the Knesset based on what are known as closed party lists. In other words, when an Israeli citizen votes in a Knesset election, he or she votes for a particular party, not for an individual representative. Different parties choose their slate of representatives in different ways, but the individual voter does not get to select individual representatives on election day.

As a result of this system, no party has ever received the necessary majority (sixty-one seats) to form a government on its own. In this respect, Israeli governments have always comprised multiple parties, or, in other words, they are coalition governments. Occasionally, parties have been able to form “minority” governments (a coalition of fewer than sixty-one seats) with the support of Arab parties that vote with the government but are not formal members of the coalition. At the same time, the relatively low threshold necessary to gain entry into the Knesset has also resulted in the proliferation of numerous small parties into the Knesset and in the Israeli political system as a whole. There are parties representing all different groups of Israeli society, ranging from religious to secular, right wing to socialist, and parties that specifically represent Arab citizens. Generally, however, Israeli politics has been dominated by large left-leaning parties (e.g., Labor and its predecessors) and right-leaning parties (e.g., Likud and its predecessors), with smaller parties and religious parties floating between the larger parties to create the government coalitions.

As the parliament, the Knesset is responsible for writing and passing legislation. Bills must pass three readings before they are signed into law. There is no process of judicial review. However, existing legislation may be amended or canceled by the passage of a new bill. Additionally, there is no authority that has power to veto legislation that is passed by the Knesset. While the Knesset has supreme legislative authority, in matters concerning “personal status,” such as marriage, divorce, or burial, it is the various religious denominations that set the rules, based on their own religious laws. In other words, the Jewish authorities regulate marriage and divorce for Jewish citizens, the Muslim religious authorities do the same for Muslim citizens, and the Christian religious authorities for Christian citizens.

As a parliamentary system, the prime minister is usually the head of the largest party in the Knesset. However, in an attempt to create more stability in the Knesset and the governments, between May 1996 and March 2001 the prime minister was directly elected separately from the rest of the Knesset. The election did not have the intended consequences, however, and many argued that the “reform” was a resounding failure. The direct election provision was quickly repealed, and the prime minister is again the head of the largest party in the Knesset.

KNOWLEDGE

If someone asks, “What is knowledge?” science seems a likely answer. Its impact is enormous, and its method is logical and rigorous, immunized from personal bias, and based on repeatable experiments revealing predictable

facts of the universe. But can one live by science alone? One should not overlook the “who-why” question: “Who wants to know, and why?” The twenty-first-century economy seems even more dependent on knowledge than when the extracting and producing industries were dominant and natural science seemed all one needed to know. Now the economy comprises “knowledge workers,” information technology, intellectual property, collaborative networks—to say nothing of laws, customs, culture, and the other aspects of social life—so it is probably even more important to understand what the term knowledge means.

The study of knowledge is epistemology, a type of philosophizing that differs from metaphysics, logic, aesthetics, or ethics. From Plato (427–347 BCE) one learns that knowledge is “justified true belief.” When one believes something to be true, the burden of demonstrating it as knowledge rather than mere opinion falls on how it is justified or “warranted.” In René Descartes’s (1596–1650) time, “full justification” was taken to mean that a statement was certain beyond doubt. Knowing that the senses can be deceived, Descartes attacked our knowing with radical doubt. He argued that only our own thinking is unmediated by the senses, so our only certainty is the mind’s certainty of itself. This positioning of reasoning cut through millennia of muddled debate and established knowledge as the antithesis of doubt, rather than the achievement of certainty. But epistemology has struggled ever since with the damage done: a loss of innocence spawning a plurality of epistemologies, each defining doubt and knowledge differently. We shall look at knowledge through this multi-epistemic prism, focusing on doubt and outlining the types of knowledge emerging, and conclude with their integration. Rather than merely list the knowledge types spoken of today (explicit, tacit, social, individual, practical, emotional, etc.), our analysis proposes a framework for their mutual constitution.

Descartes presumed that thinking should be logical; operating correctly, the mind is computer-like. This view sets emotion, also unmediated by the senses, in opposition to cold reason, dismissing emotion from knowing. Second, with both sense-data and emotion dismissed, there can be no knowledge of the world beyond the mind’s computations—for example, of the physical world in which the brain seemingly exists. So what can be known is of no relevance to our world, and what is certain is so because it is tautological, like a mathematical proof. Given these assumptions, this conclusion is inescapable. Knowledge is also individual, private, within the mind, and detached from the interests, discourses, and activities of our fellows, denying Francis Bacon’s (1561–1626) maxim that “knowledge is power.”

Logicality is powerful justification, but alone it demands too much. Scientific knowledge is a compromise between logic and other warrants that allows knowledge of the world beyond Cartesian tautology without demanding certainty. Instead of entirely removing doubt, science treats doubt as pervasive, a condition to be managed. Reaching beyond the mind, all doubt-managing, as opposed to doubt-rejecting, epistemologies take off from assumptions about what and where we are—thinking, memorizing, observing, experiencing, and so forth—though each person orders these differently. For most people, science is a variation on realism and embraces, for instance, positivism and critical realism. Realisms presume a logical and observable reality “out there,” independent of our observing. All knowledge is of this reality. Sense-data is prioritized over what we think, over opinion. Science aspires to the facts of this reality, though, afflicted by doubt, we know our impressions are conjectures, never certainties.

In contrast to realism, idealist or interpretive epistemologies like phenomenology bring us closer to Descartes, prioritizing the mind over assumptions about reality. They presume we can never know reality’s essence, and this is not our target; indeed our senses may be incapable of capturing it. All we can know is experience and our senses’ impact on our thinking. This becomes ordered as we lay mental maps or meaning systems over our experience, capturing it as knowledge. We make this our knowledge of the world, rather than our imaginings, by using it to predict our experience. We may structure it as causal relationships, but, as David Hume (1711–1776) argued, we impose such causality; we cannot observe it at work. Knowledge as meaning takes us a step back from immediate sense-data about the objects that comprise the world and into generalizations, relations, associations, covering laws, and so forth. Though epistemologically distinct, facts and covering laws are both representations of the world. Facts make the stronger claim, purporting to describe the world as it really is, but covering laws may be more useful, describing relations or forces between the factlike objects comprising the world.

All epistemologies seek justified truth-yielding links between our thinking and the world beyond the mind, which obviously includes our brains and bodies. Each epistemology adopts different strategies to manage the doubt involved. Naive realism, for instance, proposes that the mind is in intimate contact with nature; things are what they seem to be and doubt does not enter. Knowledge is individual. Justified true belief differs, for it moves knowledge beyond the privacy of the mind, presupposing its capture in a shared language whose construction and interpretation is knowing. Scientific knowledge is intersubjective, beyond the individual, and necessarily contextualized to a specific society and located in its discursive spaces and activities—book-learning statements in libraries or at conferences, for instance.
Statements can be conjectural, as Albert Einstein’s (1879–1955) were, to be tested later, or they can be empirical, based on past experience of the world. Our hypothesizing and experimentation integrates our thinking and observing, and doubt is managed through science’s intersubjective processes, supported by open discourse, multiple experiments, statistical analysis, and criticism. Disputes about whether or not this process manages doubt adequately comprise the philosophy of science (Curd and Cover 1998). Some argue that experimental confirmations raise confidence in our conjectures. Karl Popper (1902–1994), in contrast, sought falsification, seeing logical asymmetry between verification and rejection. This is an error. Rejection depends on observation theory too, so experimentation merely compares science’s confidence in the theorizing behind the hypothesis and the observation. As neither is free of doubt, the outcome remains logically ambiguous.

The methods of science can generate knowledge of the entities comprising society, as well as of the objects and relationships comprising nature. Thus realist sociology and psychology are warrantable companions to realist physics, chemistry, and biology, but who-why questions loom larger as we move from the natural to the social sciences. In pragmatist epistemologies, the usefulness of knowledge becomes the truth criterion. Representational correctness gives way to utility or “cash value.” Pragmatism is a flavor of realism in that it takes the world’s existence for granted, though this world is social, technological, and political, rather than that of the natural scientist. Jürgen Habermas integrated pragmatism with our presumed common rationality to locate knowledge in the intersubjective discourse of the democratic “ideal speech situation,” where knowledge is consensual and directed toward our interests, such as changing the lived world (Habermas 2003).

Reintroducing peoples’ interests inclines us to think reflexively of ourselves as knowing. Given doubt and a pragmatic point of view, it may be more useful to know why someone acted as they did than to know the facts of the situation they faced. Two things are going on here. First, as an actor’s knowledge is never free of doubt, there is a crucial difference between the facts and the actor’s perception of them. Instead of knowing the causes that move people as objects, we seek the actor’s perceptions and explanation of the situation. But this admits heterogeneity, for we know with all the force of cogito ergo sum, that people and their knowing differ. Second, doubt is transformed into the necessity to choose. Since reality cannot speak to us directly, we choose how to attend to and interpret the world. This choice transforms the relationship between the actor and the actor’s knowledge, for this is now more than a representation to be applied through rational decision making; it is shaped by the actor’s values and intentions, and so by his or her emotions. Doubt and emotion become integral parts of our agency and interest in changing the world. When things are certain, our actions are wholly determined; we have no options, no way of manifesting ourselves in the world. Thus doubt, emotion, variety, and diversity challenge our notions of knowledge as universal.

Science works hard for universality, and, given doubt, agreement across the community of scientists becomes a proxy for objectivity and truth, seemingly limiting the impact of emotion. But the relativism implicit in perception raises subjective doubt, not so much separating the mind from the thing known as separating people, in their knowing, from each other and undercutting the idea of knowledge as intersubjective and shared. Once admitted, intersubjective doubt needs to be managed if we are to escape epistemological anarchy and the conclusion that knowledge is whatever one wishes it to be. The openness of scientific discourse seeks convergence, or at least some form of epistemological democracy. Rejecting naive realism or a “correspondence theory” of knowledge can lead to the universal consensuality of Habermas or, within a discipline, a Kuhnian paradigm that presumes that right-thinking scientists are in broad agreement. This “social constructionist” discourse institutionalizes scientific knowledge or, rather, manages doubt and emotion in institutionalized ways (Gergen 1994). Historical studies like Thomas Kuhn’s (1922–1996), or those of sociologists of knowledge like Karl Mannheim (1893–1947) and Robert K. Merton (1910–2003), suggest that socially constructed knowledge may change sharply and unpredictably, like an ecology, and that the politics and clashing interests of the group may shape both its changes and what the group defines as knowledge. Power penetrates the discourse and process of justification.

Thus far this entry has touched on three principal modes of justification: reality, social agreement, and utility. All such post-Enlightenment epistemologies embrace reason and empiricism and stand against the transcendentalism that preceded them, when, perhaps, holy books or the Delphic oracle were the warrants for knowledge. These epistemologies also presuppose constancy of situation, reflecting the realist’s assumption of nature’s invariance. Will what was useful yesterday be useful tomorrow? Just as we know we differ, so we know situations change. Absent doubt, of course, we would be at that Archimedean fulcrum of equilibrium and truth from where we would understand change as the world’s dynamic, just as we understand a clock in spite of its moving hands. But the phenomenological drift contradicted the idea of knowledge as just about the world “out there,” turning us toward the notion of knowledge as more about ourselves and our agentic choices. Just as we become what we eat, we become what we choose to know. Knowledge
Knowledge

is us, and this is clear for today's knowledge-intensive professional. But if by *us* we mean only what we think, we fall into the chasm of relativism that terrorizes all epistemologies. Social conformance might save us, implying that we become a member of a society or a profession as and because we share its body of knowledge. But knowledge's susceptibility to power and history makes us cautious. Is there a more justifiable basis for justification? Pragmatism's usefulness criterion seems a good way to go, but it is tricky to establish ahead of the action to be evaluated. Still, it brings justification back to us and our intentions.

Given doubt, and not finding definitive invariance in nature or social reality, we presume it in ourselves. Only then can our knowing be carried from one instance to another. This takes us back to the model of humans on which our epistemology stands. But as we probe our agency, we find imagination as well as rationality. Doubt attacks reasoning, interfering with computation and action; the computer freezes, yet we act anyway. John Locke (1632–1704) attributed this to “judgment,” our native facility to arrive at conclusions in the absence of certain knowledge, that is, under conditions of doubt. To this point, what we might mean by “not-knowledge” has been dismissed as emotion or as falsified or undiscovered knowledge. Lockean judgment, on the other hand, implies forms of knowing beyond that captured in language. This suggests two things. First, as we negotiate the lived world we draw on these extra-linguistic forms of knowing. Second, knowing is no longer the application of knowledge abstracted and brought into the reasoning process; it is more intimately wrapped into the immediacy of living. Knowing is more than representing. It includes dealing with the unrepresented aspects of being in the world. Our knowing becomes who we are, integrating a complex of memorized facts and meanings, our ability to compute, and our ability to imagine as doubt intrudes and memory or reason fail. We redefine knowledge as our identity as we engage in effective practice.

The search for objectivity is also the observer's search for a vantage point outside and abstracted from the practice of living. Knowledge is what is left behind as the observer withdraws. In contrast, the phenomenological attitude ultimately draws us into the world, suggesting an engagement and intimacy of practice that generates a different kind of knowledge—the actor's epistemology proposed, for example, by Edmund Husserl (1859–1938) and Martin Heidegger (1889–1976). As we consider the action of the imagination as it deals with the experience of doubt, we move toward constructivist views, the idea that the only world we can know is the one we ourselves have constructed, that knowledge itself is a construction, a set of tools for dealing with living in the world. The critique must be equally applied to our assumptions about ourselves. While senses, reason, and imagination may be necessary conditions for consciousness and agency, they are not sufficient. Our sense of ourselves is also a construction of these components and, penetrated again by doubt, we never know ourselves with certainty or completely.

Following the work of Michel Polanyi (1891–1976), it has become common to use the description “tacit” to point to this extralinguistic form of knowing, covering both the ability to act under conditions of doubt and, reflexively, to bridge the gap between our sense of identity and our doubting self-knowledge. What we mean by knowledge must cover both what is known explicitly, justified true belief about the natural, social and psychological entities comprising our world, and what we know tacitly, only evident in our ability to act and sustain our identity living under the normal conditions of doubt and uncertainty. Constructivist epistemologies, such as Ernst von Glasersfeld's (1995), show that constructing the world also sets its boundaries, the limits to what can be known about what we might refer to as the context of our situated knowledge. Ludwig Wittgenstein (1889–1951), who considered all truth to be carried in language, saw practice as giving language meaning. If individuals are the only agents, then constructivism is individual. But others see knowledge and agency as intersubjective and see groups, organizations, and societies as agentic, suggesting social or collective constructionism (Nelson and Winter 1982). So to the previous modes of justification—reality, social consensus, and utility—we can add efficient practice and identity. Practice is a complex—either the deductive application of reason and explicit knowledge, or the constructive application of our judgment or imagination that indicates our tacit knowledge. The pragmatist's utility criterion turns out to be far from project evaluation, performed from a point outside the practice itself. On the contrary, the constructivist view presupposes the instantly-instant co-construction of meaning, context, and identity.

This multi-epistemic snapshot summarizes our different types of knowledge: realism suggests knowledge as data about the world "out there"; cognition focuses on the explicit systems of meaning we impose on our experience; while the immediacy of phenomenism focuses us on various forms of practice, individual and collective, and the distinction between reasoning and imagining. Mnemonically we can distinguish knowledge-as-data from knowledge-as-meaning and knowledge-as-practice. In the same way that knowing embraces both what is known, memorized, and recoverable for abstract computation, it also includes the self-based judgment to cope with doubt. Practice embraces both the execution of rational plans and the recursive co-construction of self and context. Emotion is an aspect of that response, and emotional knowledge comes from observing the construction of self and being.
able, pragmatically, to apply that to the agentic process (Nussbaum 2001).

Today’s knowledge-intensive lives entail integrating our knowing across these distinctions, imaginatively coping with the disjunctions and distinctions entering our thinking with our epistemology-originating assumptions. Integration comes into sight as we appreciate that each type of knowledge presumes the other. There can be no mind without the brain, no knowledge without the mind, no meaning or living without practice, no data without meaning, and so forth. Each mode of justification entails the others. To grasp today’s meaning of “knowledge” we must first admit the multiple epistemologies spawned by Cartesian doubt while realizing our ability to traverse the void of doubt between them by deploying our native creativity to construct life’s seeming coherence. Knowing harnesses our imagination and reason to our senses, memory, and language as we reach out agentically to our fellows. From this vantage point, our knowing is part of our consciousness and identity, but all of a piece, embracing knower and known, as each epistemology reflects its unique axiomatic emphasis as an analytic tool, disparate elements in our doubt- pervaded toolkit.

KNOWLEDGE, DIFFUSION OF

Diffusion suggests a drop of color in water, spreading until uniformly distributed. Knowledge, such as the cause of a disease, can diffuse until “everybody knows.” Diffusion is less specific than communication, and seems driven by the inherent tendency for the differentials between knowledge and ignorance to disappear, just as heat differences decay and entropy rises. But managing diffusion may be very different. Instead of knowledge moving under its own impulse, seeking equilibrium,
Knowledge needs to be “pushed” or “pulled.” It may be “sticky,” as if in a frictional medium; pressure is required to make knowledge flow. At other times, knowledge seems “slippery,” and one struggles to prevent leakage. Knowledge is inherently diffusible because of its nonrivalrousness, there being no loss of knowledge by those who already have it as it is diffused to others who do not.

Stickiness and slipperiness seem inherent properties of different types of knowledge. But diffusion may be more shaped by the relationship between the knowledge being moved and the context or medium through which it is moving. Stickiness implies antipathy, whereas slipperiness implies a mutuality of context, a readiness to take up and move the knowledge along, as when rumors fly. Contexts can be local, as when one department resists sharing knowledge with another, or broad, as when new political ideas spread like wildfire.

The heterogeneity of diffusion contexts is explored in network theory. Early research reflected communications technology and distinguished “star” or “radial” networks from “wheel” and more complex interconnections. Recent research focuses on social systems and social capital, when the context of knowledge flow is shaped by political, social, or economic power, or by interconnectedness (centrality). Horizontal and vertical knowledge diffusion imply transfer between equals versus transfer between those with different social power or degrees of centrality. “Small world” or “scale-free” structures are particularly interesting, suggesting people are closer and knowledge flows more rapid than were social networks randomly connected (Watts 2003).

But people ignore questions like “what is knowledge?” and “what flows?” (Ryle 1949). Knowledge cannot be understood simply in contrast to ignorance, for that would require a person to know ignorance too. Knowledge is revealed by contrasting types of knowledge. The explicit/tacit distinction is often invoked to “explain” stickiness (e.g., Szulanski 1996; Boisot 1998), presuming a normal context is sympathetic to explicit messages but less so to tacit knowledge. Yet in other contexts, explicit knowledge may be sticky and resisted, and tacit knowledge slippery. The explicit message “smoking kills” is well known, but apparently not in ways that greatly affect the behavior of smokers. Child abuse is often based on cycles of slippery tacit knowledge-diffusion that seem difficult to break. In short, analyses of the diffusion of the “knowledges” shaping human behavior must consider both the heterogeneity of the modes of knowing and of the contexts of that knowing. Thus the analysis of knowledge diffusion calls up epistemological assumptions about human beings and the world to be known, and their interaction.

For many, knowledge is about gathering data about the world “out there.” Data can be diffused or moved so long as the underlying notion of that world is shared and stable. Knowledge-as-data contrasts with knowledge-as-meaning, the lens that is put over data to make sense of it, to make it accessible to analysis. Meaning is about people rather than the world of facts, and diffusing it is different from diffusing data that fits within a shared meaning system. Language can only inform those who already speak it, and Ludwig Wittgenstein (1889–1951) argued that practice is the key to meaning. Data and meaning are mutually supporting and are tied together in information. Both are mental and imply stepping back and reflecting on one’s experience of the world. But practice, in contrast, is in the world and the instant. Tacit knowledge is important because it draws attention to this third type of knowledge, knowledge-as-practice, which lies beyond data plus meaning.

Diffusing data means helping the receiver distinguish, within an agreed field of possibilities, the noted from the unnoted. But to diffuse meaning, you rely on receivers to add something of their own construction; you can only send data to another. Even more creative, to diffuse your practice, you rely on receivers to cope with the unique moment and context of their activity and construct practices that emulate yours. Thus practice is always embedded in its context and cannot be transferred to another. Diffusion means creating a new practice, guided rather than determined by prior practice.

KNOWLEDGE SOCIETY

The term knowledge society refers to a society in which the creation, dissemination, and utilization of information and knowledge has become the most important factor of production. In such a society, knowledge assets (also called intellectual capital) are the most powerful producer of wealth, sideling the importance of land, the volume of labor, and physical or financial capital.

The term knowledge society has several meanings. First, it is used by social scientists to describe and analyze the transformation toward so-called postindustrial society. Second, it is used to refer to a normative vision that nations or companies should aspire to fulfill. Third, it is used as a metaphor, rather than a clear-cut concept, under which various topics are examined. In many cases, the distinction among these three usages is blurred, and it is not clear whether the author using the term is putting forward an analysis of current trends, is forecasting changes, or is proposing a strategy that should be followed.

Although the term is frequently evoked, it is rarely defined and explored in a systematic way. However, the key characteristics of a knowledge society can be outlined as follows: (1) the mass and polycentric production, transmission, and application of knowledge is dominant; (2) the price of most commodities is determined by the knowledge needed for their development and sale rather than by the raw material and physical labor that is needed to produce them; (3) a large portion of the population attains higher education; (4) a vast majority of the population have access to information and communication technologies and to the Internet; (5) a large portion of the labor force are knowledge workers who need a high degree of education and experience to perform their job well; (6) both individuals and the state invest heavily in education and research and development; and (7) organizations are forced to innovate continually.

EVOLUTION OF SOCIETAL DEVELOPMENT

All societies have rested on knowledge, and knowledge has always played an important role in the rise of prosperity and social well-being. Why then should we speak of this emerging type of society as a "knowledge society"? It is useful to contrast a knowledge society with previous types of human society that were based upon the dominant mode of production and the most common source of livelihood.

In a hunting and gathering society, the earliest societal type, people gained their livelihood from hunting, trapping, fishing, and gathering edible plants growing in the wild. About 8000 BCE, some hunting and gathering groups began raising domesticated animals and cultivating fixed plots of land. This domestication revolution led to the advent of horticultural and pastoral societies. A pastoral society is a society in which the primary means of subsistence is domesticated livestock, whereas in horticultural societies the primary means of subsistence is the cultivation of crops using hand tools. Many societies were pastoral and horticultural at the same time. The replacement of horticulture by agriculture is associated with the invention of the plow in about 3000 BCE in Mesopotamia and Egypt. This process, sometimes called the agricultural revolution, made large-scale agricultural production possible and led to the development of agrarian societies. The agricultural revolution had such a profound impact on society that many people call this era the "dawn of civilization."

During this period, not only the plow, but also the wheel, writing, and numbers were invented. Nevertheless, in an agrarian society, land and livestock were the key resources.

Agrarian societies, in which most of the population was directly engaged in the production of food, began to be replaced by a new societal type around 1750 at the dawn of the Industrial Revolution. Industrial Revolution is a shorthand term for a complex set of technological innovations that led to a dramatic change in the nature of production in which machines replaced tools and inanimate power resources (such as steam and electricity) replaced human or animal power. Productivity and wealth creation in an industrial society is based upon the mechanized manufacturing of goods, or, more specifically, upon the extensive and organized use of machines in factories. In an industrial economy, physical assets such as steel, factories, and railroads are the key factors of production. A large majority of the employed population works in factories and offices (while the proportion of the population engaged in agriculture rapidly declines). In addition, people are geographically concentrated. Because most jobs can be found in towns and cities, people move to cities, and industrial society becomes highly urbanized.

THEORIES OF POSTINDUSTRIAL SOCIETIES

Since the 1960s, many authors have suggested that we are entering into a type of society beyond the industrial era altogether. The first comprehensive description of the so-called postindustrial society was provided by Daniel Bell (1973). According to Bell, service occupations grow at the expense of those producing material goods, and white-collar workers come to outnumber blue-collar workers employed in factories. Work in services generally requires more knowledge and intellectual ability than work in industrial occupations. Bell also argued that theoretical knowledge is the main strategic resource of society, and those who are concerned with its creation and distribution (scientists and professionals of all kinds) become the leading social group, replacing industrialists and entrepreneurs.
Some scholars have challenged Bell’s ideas. First, his theory rests upon the now-obsolete distinction between primary (agriculture, mining, fishing, and forestry), secondary (industry), and tertiary (services) economic sectors. In contrast to Bell’s assumption, the manufacturing sector is not declining in terms of its contribution to overall economic performance and growth. The term postindustrial is thus misleading because “industry” is neither disappearing nor losing its importance. Both within the agricultural and industrial sector, significant transformations are taking place: Even agriculture and industry are becoming more knowledge-intensive, and thus more productive. In contrast, many jobs in services are in fact blue-collar (such as a gas-station attendant), while many white-collar positions involve very little specialized knowledge.

Terms such as information society or network society have been proposed to replace postindustrial society. Such terms attempt to capture the unprecedented development and use of information and communication technologies and the fact that information generation, processing, and transmission have become the fundamental sources of productivity and power (Castells 1996). These concepts, however, have been criticized as too narrow and too oriented toward technology. Critics argue that technology is merely useless “hardware” if not accompanied by “software”—the knowledge, work, and creativity of people who actually understand, make sense of, and apply the information available. Consequently, from the late 1990s the broader concept of knowledge society came to be preferred (Stehr 1994).

CONSEQUENCES OF KNOWLEDGE SOCIETY

Empirical data reveals that some countries (especially Scandinavian and western European countries, as well as Japan, the United States, Canada, and Australia) have moved toward becoming truly knowledge-driven societies (World Bank 1998; United Nations 2005). Many other countries remain in an industrial age, while others are still essentially agrarian. Why is this so? If knowledge is considered the most productive factor, why are not all societies knowledge-based or at least heading in that direction? And how can industrial and agrarian societies become knowledge societies?

In principle, knowledge is a nonrival and nonexcludable public good: one person’s use of a particular piece of knowledge does not preclude the use of that same knowledge by others, and when a piece of knowledge is already in the public domain, it is difficult for the knowledge creator to prevent others from using it. In reality, knowledge, in contrast to information, cannot be easily acquired and applied. First, only so-called explicit knowledge can be easily transferred across time and space. Large portions of knowledge—tacit knowledge—reside in people’s minds, can be accessed on a first-person basis only, and take time to develop. Second, the effective creation and application of knowledge depends upon the broader context—culture, institutions, and governance. Knowledge must be integrated into an effective system of research institutions, innovation-driven enterprises, universities, and other establishments. Third, because knowledge is considered the key factor of production and is expensive to create, rich countries have broadened the protection of intellectual property rights (especially patents), and thus have increased the amount of knowledge that is secured and monopolized.

These factors contribute to an unequal distribution of knowledge across and within countries, a situation known as the knowledge gap. Indicators used to evaluate the development of knowledge society (such as educational attainment, investment in research and development, and Internet access) seem to show that the knowledge gap has been widening, because knowledge produces further knowledge in an ever-increasing rate, and this in turn increases productivity. It is risky for a country or company to rely largely on unskilled labor and natural resource–based goods. Countries, companies, and people who do not invest sufficiently in education and new technologies for acquiring and disseminating knowledge will find it increasingly difficult to catch up to those who did invest. Yet, investment in education and new technologies is not enough; it is also necessary to create appropriate conditions to foster innovation, creativity, and cooperation. Otherwise, negative consequences, such as brain drain (the emigration of one country’s highly educated people to other countries offering better economic and social opportunity), can be expected.

SOCIAL STRATIFICATION IN KNOWLEDGE SOCIETY

What will be the class structure of knowledge society? Who will become richer and who poorer? According to Robert Reich (1991), there is a three-tiered workforce in the most advanced economies. At the bottom are workers who offer personal services; in the middle are production workers in factories or offices performing simple, repetitive tasks; and at the top are symbolic analysts who solve, identify, and broker problems by manipulating symbols. Symbolic analysts include research scientists, engineers, lawyers, and consultants of various types, but also publishers, writers, editors, journalists, or musicians. Reich predicted that advances in technology and globalization would widen the gaps in income and opportunity between these tiers.

While symbolic analysts are globally in great demand and their income is thus steadily increasing, production
workers in advanced economies could be easily replaced by routine producers in other nations, which results in the disappearance of available routine jobs. Similarly, Peter Drucker (1994) and others speak of knowledge workers, that is, a newly emerging dominant group being employed in professions that require formal education and theoretical knowledge, as well as a different approach to work—qualifications that the industrial worker does not possess and is poorly equipped to acquire. Drucker also warned, though without details, against a potential new class conflict between the highly productive minority of knowledge workers and the majority of people who make their living traditionally. Though the future of knowledge and nonknowledge workers remains to be seen, even now there is empirical evidence that in advanced economies the number of jobs that demand only low cognitive skills is declining and that high-level skills and knowledge are substantial determinants of earnings (OECD 2000).

If knowledge workers are the leading social class economically, do they also dominate in a political and cultural sense? Who possesses control and power in a knowledge society? Can a knowledge society devolve into an Orwellian totalitarian society, where one social group is able to dominate other groups through its possession of knowledge and information? Authors disagree on this. According to Zbigniew Brzezinski (1970), we are entering into a "technetronic society," where scientific and technical elites will seize control of the essential flow of information; their claim to political power would rest on allegedly superior scientific know-how. Similarly, Alvin Gouldner (1979) forecasts the rise of a so-called "new class"—as opposed to the "old moneyed class"—that is composed of intellectuals and technical intelligentsia. This class will be bonded by similar education, culture, and language codes that facilitate solidarity between class members and enable collective political action. This "culture of critical discourse," as Gouldner terms the essential unifying attribute of this new class, functions as more than the group’s common ideology; it is its instrument of domination and control and the source of its growing power.

In contrast, Nico Stehr (2002) argues that knowledge-based occupations do not and cannot form a social class because they are found in all sectors of the economy and their job description and interests are very diverse. Moreover, in decentralized and pluralistic democracies like the United States, all policymaking actors try to legitimize their claims using knowledge and information, and for this reason they employ various experts and consultants. In turn, it is difficult to enforce any claim solely on the basis of knowledge. Although those with scientific knowledge have a high social standing, they are often questioned. The consequence is a fragile society where controlling, planning, and predicting social conditions becomes more and more difficult and where the power of formerly monolithic institutions, such as the state, the church, and the military, declines.

The basic difference between Gouldner and Stehr is an assumption of knowledge distribution and its attributes. While Gouldner believes that knowledge can be concentrated in relatively few hands, Stehr assumes that knowledge is widely dispersed, that there are various types of knowledge and they are rapidly changing. Empirical studies seem to support Stehr’s view. Though the number of experts has grown rapidly since World War II (1939–1945), they have limited influence on policymaking, except on issues of narrowly technical interest (Brint 1994).

**CONCLUSION**

If knowledge society is to be a useful term, it must be taken critically and further elaborated. There are several problems with its usage. First, it does not (and cannot) capture all aspects of modern postindustrial societies. It simply states that knowledge is the most important productive factor. Yet, any type of economic determinism should be avoided. There can be different types of knowledge societies, with different value structures, life styles, and even political systems. Similarly, modern societies can be given many other labels, such as risk society, consumption society, and so on. Second, knowledge is too broad a term and should be carefully decomposed and defined in any analysis or strategy. Third, attaining a knowledge society is not ensured but must be actively supported. Fourth, there is no clear-cut threshold from which societies become knowledge societies. It is more about processes (knowledge production, learning, innovation, and creativity) than about fulfilling static objectives.

Kohlberg, Lawrence

1927–1987

The psychologist and educator Lawrence Kohlberg proposed a cognitive-developmental theory of morality that dominated the fields of moral psychology and moral education for over two decades until the mid-1990s. Though born of a wealthy family in New York, he chose to identify himself with the oppressed, helping to smuggle Jews through the British blockade of Palestine after World War II (1939–1945). He viewed his theory of moral development as a response to Nazi Germany and the Holocaust. Despite the pervasive reliance of everyday decision-making on notions of right and wrong, good and bad, that constitute the domain of moral psychology, little empirical research had actually been done on the subject. At the time Kohlberg completed his dissertation in 1958, moral psychology in North America was dominated by theories that portrayed people as either caught in a conflict between powerful self-interest and social convention (Freudian psychoanalysis) or passively molded by social norms (behaviorism). In Freud’s account, morality was at best something to be endured in order for people to live cooperatively. On the assumption of cultural relativity, there were no morally justifiable grounds upon which to judge Hitler’s actions as wrong.

It was in Kohlberg’s seminal work From Is to Ought: How to Commit the Naturalistic Fallacy and Get Away with It (1971) that he acknowledged self-interest, cultural embeddedness, and cultural relativity (the “is”), and at the same time saw within the process of cognitive development the grounds for validating a formally more adequate and universal morality (the moral “ought”). (The “naturalistic fallacy” of the book’s title refers to the invalid derivation of the moral good from the facts of how the world is.) Extending the earlier work of Jean Piaget, he proposed three broad and universal levels of moral development that proceeded from primary self-interest (level 1: pre-conventional morality), to embeddedness within social norms and structures (level 2: conventional morality), to the highest level of developmental maturity (level 3: post-conventional or principled morality). Each of the three levels was further divided into two stages. Nature would point the way, so to speak, in differentiating higher-stage morality from more conventional views on morality, and moral development was described as proceeding through an invariant and irreversible stage sequence.

Each successive stage of moral development was made possible by increases in perspective-taking ability, with the highest, principled level taking into account the perspectives of all individuals in a moral conflict (i.e., a universal perspective). Level 3: stage 5 (the social-contract legalistic orientation) includes a number of moral principles commonly found in philosophy and professional codes of ethics. Ideal societies are those that are founded upon: (1) a free and willing participation in a common agreement (or contract) to live together in a law-structured society, (2) respect for individual rights, and (3) a utilitarian analysis of consequences to society for one’s actions. Stage 6 (the universal ethical principle orientation) was Kohlberg’s vision of ideal moral reasoning, where self-chosen, abstract moral principles of universal justice were viewed as transcending social convention and law.

To investigate moral reasoning within Kohlberg’s model, research participants are asked to discuss hypothetical dilemmas that place values into conflict (e.g., life versus law). In the most famous of these dilemmas, the protagonist Heinz considers stealing an unaffordable drug that would cure his terminally ill wife. Heinz has explored every option but comes up financially short. Should Heinz obey the law or steal the drug to save his wife’s life? For scoring purposes, the decision to steal or not steal the drug is not as important as the stage of reasoning used to reflect upon the life-versus-law conflict the story imposes. Using this procedure, a considerable body of longitudinal and cross-cultural research has confirmed that individuals do progress through Kohlberg’s stages in the proposed invariant sequence (stages 1, 2, 3, etc.).
Despite the far-reaching theoretical and practical influence of Kohlberg’s model within psychology, education, and even correctional settings, the model has not been without its strong critics. The theory has been alleged to be biased against women and non-Western cultures who were said to reason in “lower level,” social conventional terms (Gilligan 1982; Shweder 1994). Even in Western culture, few individuals reason about moral dilemmas in “high level,” post-conventional terms. The most recent version of the scoring manual has removed the highest level (stage 6) reasoning altogether—not a small deletion given that stage 6 defined the stage sequence as a theory of justice reasoning. Although many of the criticisms have been addressed, the model seems to have lost its conceptual hold within the field. In comparison with earlier published reviews of moral psychology that celebrated the legacy of Kohlberg, more recent reviews emphasize the very social, relationship, and emotional-personality factors that he sought to exclude from the moral domain. Nonetheless, his work remains an important foundation within the field.

KOOPMANS, TJALLING

1910–1985

Tjalling Charles Koopmans, who shared the 1975 Nobel Memorial Prize in Economic Sciences with Leonid Kantorovich (1912–1986), was born in Graveland, the Netherlands. Koopmans studied mathematics and physics at the University of Utrecht (MA, 1933, publishing a paper on quantum mechanics) and mathematical statistics at the University of Leiden (PhD, 1936). His pioneering dissertation introduced concepts developed by R. A. Fisher (1890–1962) and by Jerzy Neyman (1894–1981) and Egon Pearson (1895–1980) in probability theory and statistical inference into econometrics, which he published in English (Koopmans 1937). He studied economics and econometrics with Jan Tinbergen (1903–1994) at the University of Amsterdam in 1934 and for five months with Ragnar Frisch (1895–1973) in Oslo. At Frisch’s request, Koopmans lectured in Oslo about statistical inference, but Frisch did not accept the case for using probability models in econometrics put forward by Koopmans and by Frisch’s student Trygve Haavelmo (1911–1999).

Koopmans took over Tinbergen’s classes at the Rotterdam School of Economics in 1937 when Tinbergen moved to Geneva to conduct his League of Nations study on statistical testing of business cycle theories. Koopmans then took Tinbergen’s place in Geneva upon Tinbergen’s return in 1939. Koopmans moved to the United States in 1940 (eventually taking U.S. citizenship), where he was employed as a research assistant at Princeton, an instructor in statistics at New York University, an economist with a Philadelphia insurance company, and from 1942 a statistician for the British Merchant Shipping Mission in Washington, D.C., analyzing optimal routing of ships.

In 1944 Koopmans became a research associate with the Cowles Commission for Research in Economics at the University of Chicago, where he was also associate professor of economics from 1946 (full professor from 1948). He succeeded Jacob Marschak (1898–1977) as Cowles research director in 1948 and became president of the Econometric Society in 1950. While in Chicago, building upon his and Haavelmo’s dissertations, Koopmans led the development of the Cowles Commission approach to the identification and estimation of simultaneous-equations econometric models, including full-information maximum likelihood (FIML) estimation, stressing that simultaneous-equations methods are better asymptotically (that is, as sample size approaches infinity) than single-equation least-squares estimation (Koopmans 1950; Koopmans and
Hood 1953). Another pioneering Cowles monograph edited by Koopmans (1951) applied linear programming methods to the analysis of production and allocation. This work was the basis for his sharing the Nobel Prize with Kantorovich, who had conducted parallel research in the Soviet Union. George Dantzig (1914–2005), another pioneer of linear programming (and a contributor to Koopmans [1951]), did not share the prize, presumably because he was a mathematician rather than an economist. Koopmans anonymously donated to a research institute associated with Dantzig what would have been Dantzig’s share of the prize money, a fact not revealed until after Koopmans died.

In 1947 Koopmans sharply criticized the empirical business cycle research of Arthur F. Burns (1904–1987) and Wesley Mitchell (1874–1948) of the National Bureau of Economic Research as “Measurement without Theory,” and he urged that empirical economists use formal economic theory as the starting point for explicit, structurally identified models (Hendry and Morgan [1995] reprint Koopmans’s review article, together with his subsequent exchange with Rutledge Vining). This methodological controversy worsened relations between the Cowles Commission and other University of Chicago economists, especially Milton Friedman (1912–2006), once Burn’s doctoral student, who insisted that Mitchell’s approach was also a valid form of economic theorizing. When Koopmans was scheduled to go on sabbatical (to write his Three Essays on the State of Economic Science), James Tobin (1918–2002) of Yale was invited to succeed him as Cowles research director. When Tobin declined to leave Yale, the Cowles Commission (including Koopmans) moved to Yale in 1955 as the Cowles Foundation for Research in Economics. Koopmans, a professor of economics at Yale from 1955 until his retirement in 1981, succeeded Tobin as director of the Cowles Foundation from 1961 to 1967.

Following his critique of NBER methodology, Koopmans’s Three Essays (1957), his most widely read work, offered a positive statement of his own methodology. The first essay argued that the use of more fundamental methodological tools reveals the common logical structure of economic theories of diverse origin. The second urged “a clearer separation, in the construction of economic knowledge, between reasoning and recognition of facts, for the better protection of both” (Koopmans 1957, p. viii). The concluding essay speculated on the future interaction between tools of analysis and choice of problems in economics. Koopmans’s later research concentrated on the normative analysis of optimal economic growth and on the incorporation of exhaustible natural resources into growth theory (Koopmans 1970–1985; Gordon et al. 1987; Werin and Jungenfelt 1976, Pt. II).

KOREAN WAR

On June 25, 1950, North Korea’s invasion of South Korea transformed a civil conflict under way since the end of World War II (1939–1945) into a conventional war. In
April 1945, U.S. president Harry S. Truman (1884–1972) abandoned a trusteeship plan for the restoration of Korea’s sovereignty after forty years of Japanese colonial rule. His quest for unilateral U.S. occupation, after an atomic attack forced Japan’s prompt surrender, ended when the Soviet Union entered the Pacific war, resulting in the last-minute decision to divide Korea at the 38th parallel into zones of occupation. The failure of negotiations to reunite Korea led to the creation in 1948 of an authoritarian government under Syngman Rhee (1875–1965) in the south and a Communist regime under Kim II Sung (1912–1994) in the north. Both Koreas were obsessed with reunification, resulting in major military clashes at the parallel during the summer of 1949. Washington and Moscow, however, opposed their clients’ plans for invasion until April 1950, when Kim persuaded Soviet premier Joseph Stalin (1879–1953) that an offensive would spark an internal uprising and bring swift conquest of the peninsula.

At first, Truman hoped that South Korea could defend itself with U.S. air support and more military equipment, actions that the United Nations endorsed in resolutions calling for a ceasefire and assistance for South Korea. Commitment of U.S. ground forces came after General Douglas MacArthur (1880–1964), the U.S. occupation commander in Japan, visited the front and advised that the South Koreans could not halt the advance. Overconfident U.S. soldiers would sustain defeat as well, retreating to the Pusan Perimeter, a rectangular area in the southeast corner of the peninsula. On September 15, MacArthur staged a risky amphibious landing at Inchon behind enemy lines that sent Communist forces fleeing back into North Korea.

Mao Zedong (1893–1976), leader of the People’s Republic of China (PRC), viewed the U.S.–South Korean reunification offensive that followed as a threat to China’s security and prestige. In late November, Chinese “volunteers” attacked en masse. After a chaotic retreat, UN forces counterattacked in February 1951 and moved the line of battle just north of the parallel. MacArthur wanted to widen the war to China, but Truman instead sought a ceasefire and then relieved the general for publicly ridiculing this policy. By June 1951, fighting had reached a stalemate.

Negotiations to end the war began in July 1951, but, after steady progress toward a truce, stalemated in May 1952 over the issue of repatriation of prisoners of war. Peace came because of Stalin’s death in March 1953 rather than a U.S. threat to use nuclear weapons against China. An armistice in July ended a brutal war that killed nearly three million combatants and Korean civilians. Almost as destructive was the conflict’s impact on world affairs. Still divided, Korea would remain a source of tension threatening regional peace. Sino-American relations were poisoned for twenty years, especially after the United States persuaded the United Nations to condemn the PRC for aggression in Korea. For Japan, Korea not only ignited economic recovery, but led to treaties restoring sovereignty and establishing a security alliance with the United States. Hailed as an example of collective alliance, the war instead severely strained relations between the United States and its allies, not least because it ensured the survival of odious regimes on Taiwan and in South Korea. Most important, the Korean conflict intensified the cold war, motivating huge increases in U.S. defense spending, the rearmament of West Germany, and the militarization of the North Atlantic Treaty Organization.

KROEBER, ALFRED LOUIS

1876–1960

Alfred Louis Kroeber earned the second PhD awarded in anthropology in North America, and is regarded as a founder of the modern discipline. He was born in
Hoboken, New Jersey to well-to-do German-speaking parents. Although his family is often described as Protestant, Kroeber attended the Ethical Culture School, which though officially nonsectarian was associated with a secular humanist strand of Judaism. He studied English at Columbia College, switching to anthropology after meeting the charismatic and forceful Franz Boas. His twenty-eight-page dissertation “Decorative Symbolism of the Arapaho” (1901) was an analysis of specimens he collected for the American Museum of Natural History. Kroeber spent his academic career in California, where he established the Department of Anthropology at the University of California at Berkeley and directed what became the Museum of Anthropology there. He retired in 1946, but remained active in the field until his death.

Kroeber married twice. His first wife, Henrietta Rothschild, died in 1913 of tuberculosis. He married Theodora Kracaw Brown in 1926, and adopted her sons, Theodore and Clifton, from an earlier marriage. Theodora and Alfred had two more children, Ursula and Karl. The Kroebers were an academic and literary family. Theodora published many books, including *Ishi in Two Worlds* (1961), a biography of a California Indian. Alfred Kroeber's relationship to Ishi has recently become a controversial subject addressed in *Ishi in Three Centuries* (2003), a collection of scholarly articles edited by sons Karl, a professor of literature, and Clifton, a historian. Kroeber's daughter is the science fiction and fantasy writer Ursula K. LeGuin.

Alfred Kroeber regarded anthropology as a method for doing history. His academic research and writings addressed two broad concerns: theorizing the nature of culture, and delineating the boundaries of and patterns within specific cultures. In the case of the latter, this can be appreciated in his archaeological investigations in Nazca, Peru, through which he contributed to the archaeological concept of seriation, or relative dating, by observing stylistic changes over time. Cultural boundaries figured into his work on the culture area concept published in *Cultural and Natural Areas of Native North America* (1939), whereas patterns within cultures was the subject of his much criticized *Configurations of Culture Growth* (1944). In both works he developed typologies of cultures based on compilations of traits. For Kroeber, a culture was something analogous to grammar: Both were composed of unconscious mental rules or patterns that could be discerned and described.

Perhaps Kroeber's most controversial idea concerned his concept of culture generally. In a 1917 article published in *American Anthropologist* he described culture as "superorganic," an entity that existed apart from and independent of individuals. It was not inherited, only transmitted socially. In other words, culture caused culture. One corollary of this was that individuals and individual variation were inconsequential to describing specific cultures. The trouble with this position is that it ignores the context in which people, the culture bearers, live. The problem is illustrated in a story told by the late George Foster, a founder of medical anthropology and one of Kroeber's students at Berkeley in the 1930s. As a young graduate student Foster was expected to learn how to collect ethnographic data by interviewing an elderly member of a northern California Indian tribe, a man who had been Kroeber's informant many years earlier. As required, Foster traveled to northern California and conducted a series of interviews about "Native culture" with the old man. Finally, the elder told Foster he would have to stop the interviews as he was becoming exhausted from reading Kroeber's *Handbook of the Indians of California* (1925) every evening in order to have something to tell Foster each day.

Kroeber's understanding of culture as monolithic also informed his relationship with the Native California man known as Ishi (c.1860–1916). Ishi was the sole survivor of a group of northern California Indians hunted, harassed, and dislocated by white ranchers and other settlers. In 111, alone and starving, Ishi came into the town of Oroville, where he was jailed and then turned over to Kroeber's Department of Anthropology. Kroeber, like others in that era, believed Ishi to be the "last wild Indian," and therefore to be in possession of culture uncontaminated by "civilization." Kroeber arranged for Ishi to live and to be a living exhibit at the University of California museum. Kroeber also arranged for his academic colleagues, T. T. Waterman and Edward Sapir, to "work" with Ishi to record his culture and language. The story of Ishi's life in San Francisco is well told in a film made for public television, *Ishi, The Last Yahi* (1992). Ishi died of tuberculosis while Kroeber was in Europe, and despite Kroeber's supposed directive to the contrary, his body was autopsied "for science." Kroeber himself sent Ishi's brain to the National Museum of Natural History of the Smithsonian Institution. The whereabouts of Ishi's brain and Kroeber's role during Ishi's last years of life became a controversy in 1999. Eventually, the brain was removed from the museum and was buried with Ishi's cremated remains in northern California in 2000.

Kroeber's actions and his academic work show him clearly as a man of his time. Despite theoretical and methodological shortcomings now apparent in his work, Kroeber rightly deserves recognition for his contributions to the discipline of anthropology: He published more than 600 scholarly articles and books; along with Boas, he is responsible for institutionalizing anthropology as a university-based discipline; and most significantly, he established culture as the primary object of North American
anthropological inquiry, where it remains a productive subject for social theory.

KSHATRIYAS

The word Kshatriya (from the Sanskrit ksatra, meaning “power”) refers to the military and administrative subdivisions of South Asian society that arose by the first millennium BCE and those who claim descent from them. It is the second of four varnas (commonly known as castes) in an idealized Hindu social order. Despite shifting political configurations under and after colonialism, the designation Kshatriya remains potent as a status marker in the Indian Subcontinent and, to a lesser degree, Southeast Asia due to its prestigious ritual entitlements and literary associations.

Although the word itself is not used, the earliest reference to Kshatriyas as a ruling class appears in the Rig Veda (c. 1000 BCE), a sacred text whose codification was roughly contemporaneous with the ostensibly occupational stratification of society in what is now Pakistan and northern India. Shortly thereafter, Vedic commentaries assigned differing sacrificial obligations, food prohibitions, greetings, funeral practices, and so on to each of the four varnas. Kshatriyas were, for example, polygamous and allowed meat and alcohol. However, recorded instances of intermarriage and occasional upward mobility between Brahmans and Kshatriyas of this period illustrate an early fluidity, as well as a tendency to group these two higher varnas together in relation to everyone else (Anand 1985).

Endogamy and Commensality prohibitions had probably taken hold by around the sixth century BCE, when Brahmans and Kshatriyas began to share competing claims to the top of the status hierarchy. The frame-stories of the philosophical Upanishads feature Brahmans at the feet of Kshatriya gurus, while the scriptures of the Kshatriya-founded Buddhist and Jain faiths contain references to and arguments for Kshatriya supremacy.

Brahmanical rejoinders appear in the Indian epics Ramayana and Mahabharata and in treatises on law and statecraft compiled in the early centuries of the Common Era. The literary record balances valorization of archetypical Kshatriyas such as Rama, the ideal king, with insistence on the superiority of Brahmans and the traditional separation of powers. Much of the conflict in the latter of the two epics, the Mahabharata, stems from the reluctance of Kshatriya characters to fulfill their royal or martial duties. This is explicitly argued in the Bhagavad Gita, where the god Krishna, himself a Kshatriya, teaches that “heroism, fiery energy, resolve, skill, refusal to retreat in battle, charity, and majesty in conduct” are qualities intrinsic to Kshatriyas, who either act accordingly or incur sin (Miller 1986, p.149). Furthermore, the epics narrate tensions between Brahmans and Kshatriyas in the story of the semidivine axe-wielding Brahman Parashurama’s extermination of the world’s Kshatriyas. This myth enabled claims, particularly in south India, that true Kshatriyas no longer exist.

A textual tradition that took shape around the same time as the epics concerned itself with the science of dharma (law, duty). In addition to a battery of distinctive ritual prescriptions and provisions for succession and alternate sources of income (trading, farming, or banking) under extenuating circumstances, the sustained reflections on the Kshatriya varna found in these sources interrogate the relationship between the Kshatriya varna and kingship. An impetus for this debate, which continued into the seventeenth century, was the rise of non-Kshatriyas to political sovereignty. A variety of positions emerged in response, with “only Kshatriyas are rightfully kings” on one end of the spectrum and “whoever rules is king” on the other (Pollock 2005). In practice, further slippage seems to have occurred such that even Muslim rulers could be considered Kshatriyas through matrimonial alliances (Alam 2004).

Varna was the primary category employed in the early censuses of the British Raj, which showed marked regional variation in the distribution and social position of the numerous subcastes (jati) anachronistically labeled
Kshatriyas and Allied Castes. While well represented in the north and northwest, Kshatriyas were fewer, poorer, and less educated in eastern and especially southern India, where some Kshatriya subcastes are now considered “backward” and eligible for quotas in the public sector under the Indian constitution (Dirks 2001). Nonetheless, numerous clerical, merchant, and agriculturalist groups around the country, viewing the census reports as opportunities to bolster their reputation, representation, and local rights, formed caste associations to lobby the state for recognition as Kshatriyas. The claims of groups that allowed widow-remarriage or dined with their purported inferiors were denied, but their desire to become known as Kshatriyas and the later use of the Kshatriya ideal to inspire bravery and patriotism by Aurobindo Ghose (1872–1950) and other Indian nationalist leaders highlights the category’s cultural capital (Varma 1904).

In 2003 American scholar James Laine’s biographical study Shivaji: Hindu King in Islamic India provoked heated and at points violent controversy in part by questioning the Kshatriya pedigree of the seventeenth-century hero. Although Oxford University Press withdrew the book from publication in Indian and issued an apology, activists in Pune, Maharashtra, assaulted local scholars known to have assisted Lane and severely vandalized the Bhandarkar Oriental Research, where Laine conducted much of his research. Soon thereafter, the state of Maharashtra banned the book and filed slander charges against Laine; all of which indicates that the Kshatriya varṇa remains extremely powerful, at least as an idea.

KUHN, THOMAS

1922–1996

Thomas Kuhn was the author of five works in the history of science, of which the most influential, The Structure of Scientific Revolutions, explores the character of scientific change. On its appearance in 1962 it became the central document for attacks on the logical empiricist account of science as the progressive accumulation of objective knowledge controlled by experimental and observational methods. Though Kuhn regretted and rejected the radical interpretation of this book, this interpretation was natural and served as the starting point for one side in a generation-long “culture war” between exponents and detractors of science’s claim to objectivity.

Kuhn’s ostensible topic was scientific change, how the broadest theories replace one another during periods of scientific revolution. Among the most important of these was the shift from Aristotelian physics to Newtonian mechanics, from phlogiston chemistry to Lavoisier’s theories of reduction and oxidation, from nonevolutionary biology to Darwinism, and from Newtonian mechanics to relativistic and quantum mechanics. Periods of revolutionary change in science alternate with periods of what Kuhn called “normal science,” during which the direction, methods, instruments, and problems that scientists face are all fixed by what he called “a paradigm” (the term has gone into common usage). Paradigms are more than just
equations, laws, statements encapsulated in the chapters of a textbook. The paradigm of Newtonian mechanics was not just Newton's laws of motion, it was also the model or picture of the universe as a deterministic clockwork in which the fundamental properties of things were their position and momentum from which all the rest of their behavior could eventually be derived when Newtonian science was completed. The Newtonian paradigm also included apparatus, a methodology, indeed an entire metaphysics. Paradigms drive normal science, and normal science dictates the direction of scientific progress by determining what counts as science altogether.

During normal science, three sorts of empirical enquiries flourish: restating previously established observational claims to greater degrees of precision; the establishment of facts without significance themselves but which vindicate the paradigm; experiments undertaken to solve problems to which the paradigm draws one's attention. Failure to accomplish any of these three aims reflects on the scientist attempting them, not the paradigm employed.

Naturally, some disciplines are, as Kuhn put it, in "pre-paradigm" states, as evidenced by the lack of textbook uniformity. These disciplines are ones, like many of the social sciences, where the lack of commonality among the textbooks reveals the absence of consensus on a paradigm. At some points in the histories of each of the mature sciences, a ruling paradigm emerged. But it could not have done so owing to its correctness or empirical warrant. Apparently, its ascendancy must have a social explanation.

According to Kuhn, once established, the paradigm determined the outcome of empirical inquiry. It is not empirical inquiry that determines the paradigms scientists embrace. Independent of paradigms there are no empirical facts to observe. To illustrate and support this claim Kuhn cited evidence from psychological experiments about optical illusions, gestalt-switches, expectation-effects, and the unnoticed theoretical commitments of many apparently observational words we incautiously suppose to be untainted by presuppositions about the world. Here was Kuhn's most forceful direct attack on the theoretical/observational distinction that underwrites logical empiricism's account of scientific knowledge.

As normal science progresses, its puzzles succumb to what Kuhn called "the articulation" of the paradigm. A small number of puzzles continue to be recalcitrant; phenomena that the paradigm cannot explain, or phenomena the paradigm leads us to expect but that do not turn up, discrepancies in the data beyond the margins of error, or major incompatibilities with other paradigms. In each case, there is within normal science a rational explanation for these anomalies; and eventually further work turns an anomaly into a solved puzzle. Revolutions occur when an anomaly resists solution long enough to produce a crisis. As more scientists attach paramount importance to the problem, the entire discipline's research program begins to be focused around the unsolved anomaly. At some point a (usually younger) scientist formulates a new paradigm, which turns the anomaly into a solved puzzle. But revolutionaries are not behaving in the most demonstrably rational way; nor are their (usually elderly) establishment opponents who defend the ruling paradigm against their approach acting irrationally.

During these periods of competition between old and new paradigms, nothing between them can be settled by observation or experiment. Often there is little or no difference between the competing paradigms when it comes to predictive accuracy, and often the new paradigm fails to solve puzzles solved in the old one. A new paradigm disagrees radically with its predecessor. Sometimes new paradigms are advanced by scientists who do not realize their incompatibility with ruling ones. But the new paradigm must be radically different from its predecessor just so far as it can treat as a mere puzzle what the previous one found an increasingly embarrassing recalcitrant anomaly. Paradigms are so all encompassing, and the difference between paradigms is so radical, that Kuhn wrote that scientists embracing differing paradigms find themselves literally in different worlds. Paradigms are, in Kuhn's words, "incommensurable" with one another, in the sense of not being translatable one into the other, as poems in one language are untranslatable into another. And this sort of radical incommensurability underwrites the further claim that paradigms do not improve on one another, and that therefore science does not cumulate in the direction of successive approximation to the truth. Thus the history of science is like the history of art, literature, religion, politics, or culture, a story of changes, but not over the long haul a story of "progress."

Because a new paradigm is literally a change in worldview, and at least figuratively a change in the world in which the scientist lives, it is often too great a shift for well-established scientists. These scientists, wedded to the old paradigm, will not just resist the shift to the new one, they will be unable to make the shift; what is more, their refusal will be rationally defensible. Or at any rate, arguments against their view will be question-begging because they will presume a new paradigm they do not accept. What is more, there is, recall, no neutral ground on which competing paradigms can be compared. When allegiance is transferred from one paradigm to another, the process is more like a religious conversion than a rational belief shift supported by relevant evidence. Old paradigms fade away as their exponents die off, leaving the proponents of the new paradigm in command of the field.
Progress is to be found in science, according to Kuhn, but like progress in evolution, it is always a matter of increasing local adaptation. In one of the last pages of his book Kuhn wrote, “We may, to be more precise, have to relinquish the notion, explicit or implicit, that changes of paradigm carry scientists and those who learn from them closer and closer to the truth” (1962, p.170).

The consequences of this account for skepticism about science’s epistemic status were evident to Kuhn. He spent much of his career after the appearance of *The Structure of Scientific Revolutions* trying to reconcile its account of scientific change with the objectivity and cumulative character of scientific knowledge.

**KU KLUX KLAN**

Founded in Pulaski, Tennessee, in the spring of 1866 by six former Confederate soldiers, the Ku Klux Klan quickly emerged as an antiblack and anti-Republican force in the South. Following the passage by Congress of the Reconstruction Acts in 1867, Klansmen began a reign of terror, abusing, intimidating, assaulting, and sometimes murdering those who sought to create a true democracy in the former slave states. Riding across the countryside in white (and black) robes, they burned churches, schools, and the homes of former slaves and their white sympathizers.

In his fine study of the topic, Allen Trelease (1971) described this first Klan as a “conspiracy” among many whites in the Democratic Party to subdue their rivals, but historians have pointed out the lack of communication between Klan members in different states and locales during this period. Even if there was no conspiracy, there was large-scale participation. One estimate noted that in Alabama alone there were ten thousand Klan members. In 1870 and 1871, however, President Ulysses S. Grant (1822–1885) signed into law what were called the Force Acts, giving the federal government authority to protect freedmen and Republicans. The Force Acts drove the Klan underground, and the racial and political violence that occurred in subsequent years was mostly caused by white vigilante groups.

The second Klan, founded by William Joseph Simmons (1880–1945) at Stone Mountain, Georgia, in 1915, expanded the geographical reach and organizational purpose of the group. The second Klan acquired immediate legitimacy with the almost simultaneous release of D. W. Griffith’s sympathetic and successful motion picture, *Birth of a Nation* (1915), based on Thomas Dixon Jr.’s novel *The Clansman* (1905). By the 1920s, Klan rallies, complete with cross burnings, were being held in the South, Southwest, and north-central states. The city where perhaps the largest Klan rally in American history occurred was Kokomo, Indiana, on July 4, 1923, when about 100,000 Klansmen and Klanswomen gathered to celebrate the inauguration of a new Grand Wizard. The second Klan stood against foreigners, Jews, blacks, and Catholics, proclaiming “Native, white, Protestant supremacy.” In this movement to create an all-white society, the Imperial Wizard of the Invisible Empire, the head of the Klan was called, explained: “We know that we are right in the same sense that a good Christian knows that he has been saved and that Christ lives” (Mann 1968, p. 129). With a national organization and national distribution of regalia, the new message of hate attracted a large membership, estimated at several million. It was this incarnation of the Klan that neither the U.S. government nor state and county agencies, including law enforcement departments, were able to curb or drive to cover. The Great Depression of the 1930s, however, decimated its ranks. With poverty, hunger, and unemployment among millions of Americans during the Great Depression of the 1930s, the Klan’s membership declined precipitously.

Following World War II (1939–1945), several Klan organizations emerged in various sections of the country. Klan members fought against the civil rights movement in the South and were responsible for bombings, burnings, and murders in Alabama, Mississippi, and other states. In response to this violence, the Southern Poverty Law Center, a small civil rights law firm, was founded in 1971 in Montgomery, Alabama. Today, the center is internationally known for its tolerance education programs, its legal victories against white supremacists, and its tracking of hate groups. More recently, some Klansmen, including David Duke, have gained celebrity status by appearing on television talk shows. Throughout its history, however, the Ku Klux Klan has been a secret, terrorist organization dedicated to promoting white supremacy in the United States.
KUZNETS HYPOTHESIS

During the twentieth century, economists began analyzing the growth and development of economies to determine their welfare-improving effects on citizens. One of the ways these effects have been measured is by calculating the impact of economic growth on a country’s income distribution. Simon Kuznets (1901–1985) was the first economist to attempt to do this. Kuznets (1955) conducted a study into the evolution of the distribution of personal income from 1870 to the 1950s and found that the relative distribution of pretax income in the United States, Germany, and England had been gradually moving toward equality. Per capita income in these countries had been increasing over the entire period, but at some point the share of the lower-income group began increasing more rapidly than that of the higher-income groups. The developed countries saw increasing income inequality with growth, then experienced decreasing income inequality. In developing countries, however, income inequality had been increasing along with increases in per capita income.

Economic theory suggests that a higher income share among a country’s wealthy will lead to increased savings, thus increased wealth. Economic growth also usually leads to an increase in industrialization and urbanization, with an increasing disparity in income between rural and urban sectors. These trends suggest that there should be increased inequality with economic growth. Therefore, the trend toward income equality for these developed economies was a puzzle to Kuznets.

W. A. Lewis’s (1954) dual economy model provides some explanation. According to Lewis, an economy starts with unlimited supplies of labor in its agricultural sector. As the economy develops, it creates another more industrialized sector—a manufacturing sector. This change causes a movement of labor from the agricultural sector to the new sector, and leads to worsening income inequality as the new sector enjoys better returns. However, increased movement of labor across the two sectors will, in the long run, reach a turning point, causing incomes in the agricultural sector to improve and leading to greater income equality.

Another plausible explanation for the effect of development on income inequality is its effect on education and the production of human capital. At the initial stages of development, only the rich may be able to afford education, augmenting their skills and thus their income. This will increase income inequality. However, as per capita income increases and more people are able to afford education, the income of the poor will converge with that of the rich.

THE INVERTED-U HYPOTHESIS

The inverted-U hypothesis paradigm originated from Kuznets’s initial observation of the growth and distribution of income inequality in the United States, Germany, and England. Some economists argue that this theorem can be applied to all economies, and they have been using empirical evidence to prove this theorem and to determine the causal roots of this process. To be able to successfully test this theorem, however, long-term income distribution data is required. The lack of such data has led to many creative means of testing and to a lack of consensus among economists on how the hypothesis works and what happens when there is increasing per capita growth.

Felix Paukert (1973) used cross-sectional data of countries (although he acknowledged the need for long-term data) and found a tendency toward equality among developed countries, as evidenced by an increase in the share of income of the bottom 60 percent. Among developing countries, however, there is a tendency toward inequality, although Paukert was unable to offer definitive conclusions due to the lack of data in the sample. He therefore analyzed a cross section of forty-three countries and found a Gini ratio of 0.467 among developing countries and 0.392 among developed countries. Since the Gini ratio measures inequality of a distribution ranging from 0 to 1, where 0 corresponds to perfect equality (everyone has the same income) and 1 corresponds to perfect inequality (all but one person has zero income), Paukert’s findings suggest that developed countries have moved toward greater equality relative to developing countries.
Montek Ahluwalia (1976) followed up on the work of Paukert and determined the relationship between income inequality and per capita growth rate using cross-country data. His sample included sixty countries—forty developing countries, fourteen developed countries, and six socialist countries. Ahluwalia's results showed that an inverted U-shape could be fitted onto the countries at various stages of development and income inequality. However, the slope of the fitted curve changed when he looked at the sample of developing countries. These results were, however, obtained by controlling for socialist countries, because their policies tend to move countries toward development. Ahluwalia suggested that these results may be "stylized facts" for which an explanation may not be possible.

The use of cross-country regressions with countries at different stages of development is not an effective method for testing the Kuznets hypothesis. This method assumes that the turn from increasing to decreasing income inequality happens around the same level of per capita income for all countries. It also assumes homogeneity across countries. Ashwani Saith (1983) questioned whether the empirical work done to confirm the U-hypothesis is in vain. There exists diversity between countries that cannot be accounted for by controlling for whether a country is socialist or developing. A logical way to test the hypothesis may be a time series analysis for individual economies or simultaneous equations on all countries. Nonavailability of the necessary data has kept this project from being undertaken.

THE S-CURVE

Income inequality began increasing in the late 1960s and early 1970s in the United States, England, and Germany, creating yet another puzzle for economists. Rati Ram's (1991) time series study of U.S. data on income inequality from 1947 to 1987 showed that income inequality followed more of a U-shaped pattern than an inverted-U. His data do not include the earlier period of increasing income inequality. This finding has led to the S-curve hypothesis, which implies that with growth in per capita income, an economy will begin to experience increasing and then decreasing income inequality, and after a period of adjustments, income inequality will begin to rise again. Other economists have argued that the inverted-U is just repeating itself, and thus we should expect to see another period of declining inequality. However, the why and when remain unanswered.

John List and Craig Gallet (1999) analyzed data from seventy-one countries for the 1961–1992 period to test this hypothesis, and found that countries could be placed along all the turns of an S-curve. For example, third-world and developed countries are located on the upward-sloping portion of the curve, while emerging economies are located on the downward-sloping portion. Unfortunately, in addition to covering only a short time period, their data did not include all years for all countries. What they ultimately prove is the relationship between per capita income and income inequality in the world. They fail to address historical change in inequality with changes in per capita income.
Romie Tribble (1999) associated the turn from decreasing income inequality to increasing income inequality with another change in the important sector that affects economic growth. The first turning point in the S-curve can be attributed to economies moving from an agricultural to a manufacturing sector. The second turning point occurs when the service sector becomes dominant, a development characterized by increasing returns to education, thus leading to economic growth. Using U.S. data from 1947 to 1990, Tribble proved that the S-curve fit the data. The shifts in the sectors matched the years considered, but he was unable to test this finding. If his analysis is correct, it implies that some developing countries that never build up their manufacturing sector and seemingly move directly from an agricultural sector to a dominant service sector may never experience a period of decreasing income inequality.

THE CURRENT STATE OF INCOME INEQUALITY

An example of whether Kuznets’s hypothesis can be translated to other developing countries can be found in the economic growth of Asian countries, especially the “tigers.” The four big East Asian tigers—Singapore, Taiwan, Hong Kong, and South Korea—achieved high growth rates between the 1960s and the 1990s through export-driven economies. They were able to maintain this growth rate by an increasing shift to the manufacturing sector, industrialization, and improvements in education. However, armed with the experiences of developed nations, these economies offered protection for their agricultural sector in the form of better property rights and subsidies. A graph of income inequalities as measured by the Gini-coefficient over this period shows Hong Kong with a U-shaped curve, and its minimum inequality occurring in 1980 at a Gini of 0.39. Taiwan experienced declining income inequality up to the 1980s, and its Gini of about 0.29 remained fairly constant thereafter. Singapore and South Korea’s income inequality also appears to have remained fairly constant over the time period (data obtained from the UNU/WIDER World Inequality Database, Version 2.0, developed from the Deininger and Squire [1996] dataset).

Income inequality has been increasing in most countries, with the worst increases occurring in developing countries. Countries that should be experiencing decreasing inequality according to the inverted-U hypothesis do not experience it. Increases in cross-country trade, factor mobility, and the ease of capital movement across nations have led to increased globalization. Growth in per capita income could thus be occurring in a nation, but its benefits may not be realized by its population.

CONCLUDING REMARKS

Empirical work done on the Kuznets hypothesis generally begins with an assumption about what the relationship between growth and inequality should be, leading to an estimation technique that confirms the assumption. Growth in per capita income cannot fully explain changes in income inequality. Economic growth does not in itself change the income of the poor; rather, it presents opportunities for improving the population’s welfare through the policies adopted in a country. Analyzing this relationship requires a better understanding of these policies and their effects.

Another complication in this analysis is the reverse effects that income inequality could have on economic growth. Economists have theorized that more money in the hands of the rich would lead to increased investments and thus growth in the nation. However, isolating the effects of economic growth could prove daunting.

LABELING THEORY
According to the French sociologist Émile Durkheim, the broad themes of labeling theory are located in the definition of crime as necessarily relative. Other antecedents of the explicit theory include Erving Goffman’s stigma, Robert K. Merton’s discussions of innovators, rebels, and conformers, Frank Tannenbaum’s wonder at the actual normalcy of much delinquent behavior, and Edwin M. Lemert’s distinction between primary and secondary deviance. The theme of social conflict over the decision of what to label as deviant is at the heart of this concept, and scholars emphasize it repeatedly. Further, John Hagan’s work asserts that labeling theory is fundamentally concerned with the effect of the label in the process of creating the deviant career.

The work of identifying the deviant and the importance of the deviant’s label has primarily focused on crime and illness, both mental and physical, although Goffman’s general concern with stigma and spoiled identities includes attention to understanding minority identities as deviant. After acknowledging the power and consequences of the label, several authors discuss the tools people use to achieve, contest, hide, or discard these labels. In his research, William Chambliss focused on the importance of visibility in the labeling of deviants as in part a function of economic inequality. The expertise of appropriate demeanor when confronted with authorities to whom one is visible is also crucial. Others tools include reinforcement/intervention, identity transformation and reintegration, selective concealment, and negotiation and fighting back.

Although prolific in symbolic interactionist and micro-level approaches, historical analyses of the labeling process look to structural, macro-level processes, such as the change in label from serf to vagrant, and the implications of the “new” phenomenon of middle-class delinquency, understood in part as a function of a failure to label due to structural positions of particular deviants and the “informal handling and preferential treatment” they thus receive (Vaz 1967, p. 1). While not necessarily using labeling theory terminology, the law and society perspective incorporates the idea that what the law does is label and create insiders and outsiders. As well, in general social structural terms, the importance of the moral entrepreneur in re-labeling in social change efforts, such as the Marijuana Tax Act or the civil rights movement, is important.

Critiques of the theory have focused on its assumption of an overly reactive individual. Sethard Fisher argued that labeling theory improperly weighted the label, and did not pay sufficient attention to choice, opportunity, or “common pre-existing characteristics” that might lead one to commit a deviant act (1972, p. 83). This involves a focus on the preexisting in terms of an actual deviant labeling process vis-à-vis a particular instance of behavior, but it is perhaps too narrow a focus. Labeling as a perspec-
Labor may be understood to encompass attention to the interaction of a host of labels, social positions, or roles. In this early set of critiques, Hagan also posited “psychological difference” as one such preexisting difference that labeling theory does not attend to with enough rigor. However, research does support that preexisting differences such as class, race, and gender are among the prime concerns of the perspective, even if psychological differences per se are not.

Hagan's late-twentieth-century work introduced the Power-Control theory, which emphasizes inherent power relations in determining delinquent actions and what is considered deviant; for example, “the class structure of the family plays a significant role in explaining the social distribution of delinquent behavior through the social reproduction of gender relations” (1988, p. 146). This is an explicit acknowledgement of the problem of failing to live up to a variety of labels (e.g., girl, middle-class, white). However, this position does not seem to acknowledge that interaction across “vertical, hierarchical lines of power” has indeed been the major theme of labeling theory. For example, “[P]ower usually brings preferential symbolism” (1988 p. 2) seems to be another way to say, “In the eyes of the police and school officials, a boy who drinks in an alley and stands intoxicated on a street corner is committing a more serious offense than a boy who drinks to inebriation in a nightclub or a tavern and drives around afterwards in a car” (Chambliss 1973, p. 10). “What distinguishes a structural criminology is its attention to instrumental and symbolic uses of power, both in relation to criminal behavior and in the study of reactions to this behavior” (Hogan 1988, p. 2), is not unlike Nancy J. Herman's argument—albeit in the lifeworld of the ex-crazy—on such negotiations of power. Thus, the newer perspectives of critical criminology and structural criminology are in many ways permutations of the general themes of the labeling perspective: “rules are the product of someone’s initiative” and “duties are imposed upon us that we have not expressly wished. Yet it is through a voluntary act that they arose” (Becker 1963, p. 147; Durkheim 1982, p. 174). In other words, members of society must negotiate over their labels, even if they do so from within unequal positions of social power.

LABOR

Labor is one of the three primary factors of production, next to capital and land. However, different from the other two, labor deals with the work of humans rather than money or the property it can rent or buy. Being part of labor requires thus that one is paid for one's labor services.

The provision of labor was seen by the French sociologist Émile Durkheim (1858–1917) as part of the identification of a worker with society or part of the struggle of the personality with society. The laborer as the member of a class—the working class—is also a recurring theme in sociology. Two classical expositions come from the political philosopher Karl Marx (1818–1883), who offers a historical analysis of class struggle, and the sociologist Max
Weber (1864–1920), who uses class more as a classification of stratification. The reward of wages in the context of labor, especially its share of the entire production process encompassing all factors of production, also mirrors the importance and power of the class within society.

ANCIENT LABOR TO INDUSTRIALIZATION

Ancient labor markets, especially in ancient Greece and Rome, were based on agriculture and manufacturing. Both relied heavily on slave labor, which provided both skilled and unskilled labor.

In medieval times, the common agricultural laborer, or peasant, produced for self-sufficiency, and there was little exchange economy. Labor was dependent on the aristocrats, who were the landowners. The feudal landlords granted protection and the right to use the land in exchange for taxes that included labor services, which is commonly called bondage. This hierarchy from lord to serf was common from higher to lower aristocracy and from aristocrats to peasants. Extortion of both goods and labor services were enforced not only by the aristocracy’s ownership of the land, but also by their executive and judicial power.

Manufacturing, which was usually strong in the free cities (i.e., those not under the rule of an aristocrat), was in the hands of guilds whose members organized themselves to protect their interests. Workers had to learn a craft by going through the apprenticeship as journeymen, and they depended on their guild master both financially and also professionally as the guild masters decided upon elevation to the master level. While labor was in this sense not free, moving to the free cities to become a craftsman allowed one to free oneself from aristocratic rule.

Factory work forms the core process of industrialization, moving away from small-scale production at home and toward large-scale, specialized production. This specialization process is described with the example of the pin factory by the Scottish economist Adam Smith (1723–1790):

[I]n the way in which this business is now carried on, not only the whole work is a peculiar trade, but it is divided into a number of branches, of which the greater part are likewise peculiar trades. One man draws out the wire, another straightens it, a third cuts it, a fourth points it, a fifth grinds it at the top for receiving the head; to make the head requires two or three distinct operations; to put it on, is a peculiar business, to whiten the pins is another; it is even a trade by itself to put them into the paper; and the important business of making a pin is, in this manner, divided into about eighteen distinct operations, which, in some manufactures, are all performed by distinct hands. (Smith 1776, p. 15)

While Smith understood the importance of specialization, in his time the impact of machines was probably still underestimated. Mechanization using the steam engine in the eighteenth century led to a higher productivity of factory work, which is commonly seen as the breakthrough in the process of industrialization.

Smith did provide the intellectual underpinning of the capitalist model in which the pursuit of self-interest under free competition leads to higher wealth for society. His influential work was even used in English courts to prohibit union activities, as the unionization of labor was seen as a hindrance to free competition.

Together, mechanization and specialization led to a certain alienation of the laborer toward the production process. Labor became, next to capital, a true factor of modern production. During the period of industrialization, peasant workers moved away from agricultural work and toward that of unskilled labor in the newly established manufacturing plants. These laborers were no longer dependent on landowners but became wage workers, forming the working class. The process of industrialization was a long one. Exploitation of the workers was the norm rather than the exception as sufficient labor arrived from the ranks of agricultural workers. Edward P. Thompson, in “The Moral Economy of the English Crowd in the Eighteenth Century” (1971), writes of the formative years from 1780 to 1832 in England. He describes in detail the life and the movements of the English working class of that time. It was through the struggle of the workers that the notion of a working class evolved, which was necessary to develop labor organization.

It took about a century for wage labor to become the norm in the nineteenth century as increasingly more workers were employed, replacing workers on the land with work in the newly established factories. The movement from larger workshops to mechanized industries took two centuries, from the late eighteenth century into the early twentieth century. Industrialization commenced in England and was started in continental Europe several decades later, starting with Flanders, France, and later in Germany, Switzerland, and some southern European countries.

LABOR ORGANIZATION

Labor organization commenced in Europe in the eighteenth century, first within an urban setting or within factories, solely to perform the social functions of exchange and insurance against illness. National organization arose in Europe in the late nineteenth century. It was the skilled worker, at a level between owner and unskilled labor, who...
participated in the organization of labor in unions. Labor organization was not at first a reaction to hardship. In fact, the living standards of workers, unionized or not, were steadily rising throughout Europe from 1850 to 1900.

The history of unions in the United States started in the nineteenth century. In the turbulent decades from 1870 to 1890 the groundwork for organized labor was laid. The National Labor Union (NLU), founded in 1866, was the first federation of unions, followed by the Knights of Labor in 1869. The latter disintegrated after the Haymarket Riot on May 1, 1886, in Chicago in which unions unsuccessfully demanded the eight-hour working day.

The American Federation of Labor (AFL), founded in 1886, organized mainly skilled workers, while the more radical Industrial Workers of the World (IWW), founded in 1905, provided a federation for unskilled labor. The membership in the IWW declined with the Palmer Raids (1918–1921), named for Alexander Mitchell Palmer, the U.S. attorney general after World War I who led the government attack on the radical left during the “Red Scare” period.

Unions in the United States did not become a political factor in those years. This has been attributed to several reasons: The U.S. political system was fragmented between states and the federal level, and it discouraged worker movements. Furthermore, employers’ associations reacted very strongly against the labor organizations. Janet Currie and Joseph Ferrie argue in the Journal of Economic History (2000) that despite some legislative changes in favor of the laborer, unions refrained from a national political influence and instead sought to negotiate on a company level.

This changed after the Great Depression and especially under the New Deal programs of President Franklin D. Roosevelt. The labor movement was strengthened, and the government found its role in brokering agreements between businesses and labor unions. The government’s aims were to provide some assistance to poor and unemployed workers and to establish the rights of labor unions, which culminated in the Wagner Act.

During the 1930s, the Congress of Industrial Organizations (CIO) organized industrial workers who were part of the emerging large-scale corporations. This represented a movement from crafts-based unionism toward industry unions. The CIO argued that crafts-based unionism was no longer suitable to many industries in which several crafts were undertaken, thus artificially dividing the unionized workers within a firm. One union organized within the CIO was the United Auto Workers (UAW). The CIO split off from the AFL to form its own entity in 1938. After World War II (1939–1945), as most differences were settled, the two combined into the AFL-CIO, under which most unions are aligned.

NEW MODES OF PRODUCTION, LABOR SAVINGS, AND GLOBALIZATION

The 1960s marked the beginning of steady decline in union membership. After the economically strong years following World War II, workers faced increasingly more plant shutdowns. During the 1970s the fear of mechanization and the displacement of men by machines was a recurring theme. In the 1980s cheaper foreign labor began replacing domestic labor. This was most explicit within the automobile industry, in which European and especially Japanese manufacturers provided fierce competition against the American car manufacturers. Under this pressure, union power eroded over time. The fear of globalization was amplified during the negotiations about the North American Free Trade Agreement, which opened up the markets of Mexico, Canada, and the United States in 1994. The opponents feared U.S. workplaces being moved to Mexico, with cheaper labor and lower working standards. In consecutive years, intensifying trade and the outsourcing of labor-intensive industries, especially to Asian countries, weakened the union even more.

This increasing globalization was anticipated in Robert Reich’s book The Work of Nations (1991). His main theme is that the division of workers into skilled and unskilled occupations is extended to a threefold partition into routine producers, in-person service providers (services that have to be provided person to person), and knowledge workers. The last type is rather broad as it includes some people who are usually not considered part of labor, such as entrepreneurs. It is this last type of worker for whom Reich foresees the best prospects, while the routine producers in particular will be replaced either by foreign competition or machines. The in-person service workers are somewhat protected from foreign competition as they require the physical availability of labor.

While the traditional struggle between the capitalist class (the providers of capital) and the labor class seems outdated, Stanley Aronowitz argues in How Class Works (2003) that labor still struggles over institutional arrangements such as working hours, overtime pay, and working conditions. These social movements are in essence class struggles over the division of power between capital and labor. In the United States capital is still the decisive element, argues Aronowitz, as the workers did not unite the aims of the different groups (immigrants versus native, black versus white, male versus female), but Aronowitz argues labor should still strive to unite as a force in order to strongly support its common goals.
U.S. FEDERAL LABOR LAW

Labor law reflects the struggle and achievement of labor in a nation. In the United States, the following legal developments show the evolution of current laws. While not intended to forbid the labor unions, the Sherman Antitrust Act of 1890 was used for many years to hinder union work. Its unspecific nature prohibiting “combinations in restraint of trade” allowed its use against combined, unionized demands from workers. The Clayton Antitrust Act, Section 6 (1914), remedies this shortcoming as it explicitly exempts labor unions. The National Labor Relations Act, or the Wagner Act (1935), allowed union representation and established the National Labor Relations Board. It allowed for collective bargaining and strikes to enforce demands. However, the Wagner Act does not encompass all workers; agricultural workers, for example, are excluded.

The Fair Labor Standards Act (1938) enacts minimum wages and overtime pay, and it abolishes oppressive child labor. While it originally included many exemptions, over time several of those have been eliminated so the act covers all blue-collar workers while excluding supervisory functions.

During World War II, the Fair Employment Act (1941) was introduced, prohibiting racial discrimination. Initially it was intended only for the national defense industry, but it was later extended to encompass all labor relations and to prohibit many forms of discrimination in the workplace.

The Taft-Hartley Act (1947), or Labor-Management Relations Act, and the Labor Management Reporting and Disclosure Act (1959) amended the National Labor Relations Act to restrict union power. The acts prohibit unfair labor practices by unions, which were previously only prohibited for employers. Unions were no longer allowed to influence the employers in their allocation of work to different plants. Secondary boycotts—for example, the refusal to handle the goods of non-unionized companies—were also prohibited. Closed-shop agreements—that only union labor could be hired by employers—were also outlawed.

LABOR INSTITUTIONS

The International Labor Organization (ILO) was created in 1919. There were several reasons for the establishment of such an organization. Its primary concern, a humanitarian one, was for the welfare of the worker. Numerous workers in many different countries had to work under exploitative circumstances, threatening their life, health, and family life. A second purpose was to integrate the growing working class into the political process and thereby to avoid social unrest or revolutions that could impede international peace. This aim is also found in the constitution of the ILO, as peace can only be achieved along with social justice. An economic motivation for the establishment of the ILO was concern over the cost of upholding humanitarian working standards. It was generally agreed that international standards for working conditions would avoid a race to the bottom—that is, a competition among nations over low labor costs, to the detriment of the workers. The organization of the ILO is tripartite. Each member country has two representatives of the government, one of the employers’ associations, and one of the labor unions.

In 1926 the ILO introduced a supervisory system to control the implementation and enforcement of its standards. This was an important step toward a more functional organization that went beyond discussing pressing issues. The United States, which was involved in several aspects of the founding and establishment of the ILO, became a member in 1934. One of the main steps forward was the Declaration of Philadelphia, adopted in 1944, which introduced freedom of association for workers. In 1969, the ILO was awarded the Nobel Peace Prize.

The U.S. Department of Labor is the governmental organization responsible for labor in relation to occupational safety, wage and hour standards, unemployment insurance benefits, reemployment services, and labor statistics. On the national level, the Bureau of Labor Statistics is the principal organization within the United States to provide statistical information and research for the government. While it is part of the Department of Labor, it serves as an independent statistical agency and provides labor market statistics as well as occupational forecasts. Other countries have organizations that have similar goals, albeit often less extensive ones.

LABOR, MARGINAL PRODUCT OF

Consider a firm producing a homogeneous output $y$ employing labor $l$ and other $n$ factors of production: $x_1, x_2, \ldots, x_n$. The change in output resulting from the addition of one extra unit of labor, with the other inputs being held constant, is called the marginal, or physical, product of labor (MPL). Formally, assuming that the technology of the firm is described by the production function $y = f(l, x_1, x_2, \ldots, x_n)$, MPL is expressed as follows:

$$\text{MPL} = \frac{\Delta y}{\Delta l} \quad \text{(given } x_1, x_2, \ldots, x_n)$$

Broadly speaking, the concept of MPL describes the ratio of change in output stemming from a small, or "marginal," increase in the use of labor. Moreover, modern neoclassical production theory assumes that labor (and the other inputs it is combined with) can be employed at a continuous level (a realistic assumption labor is measured in "labor time"), and that the production function is continuous, with continuous first derivatives. The marginal product of labor can then be rigorously expressed by the first partial derivative of $f$ with respect to $l$:

$$\text{MPL} = \frac{\partial f}{\partial l}(l, x_1, x_2, \ldots, x_n)$$

Although the same name is generally given to the two definitions reported above—and what follows will conform to this general use—it would be more appropriate to call the former (the discrete case) the "marginal product of labor," while the latter (the continuous case) would be more appropriately defined as the "marginal productivity of labor." These definitions may be easily extended to the case of joint production, that is, when a firm, for a given combination of inputs, produces more than one output (the so-called multiproduct firm).

THE MARGINAL PRODUCT OF LABOR AND THE DISTRIBUTION OF INCOME

The concept of MPL has a central place in marginal productivity theory, since at the very core of this approach is the understanding that in a competitive market the remuneration of each productive factor should be equal to its marginal contribution to production. A direct implication is that as the relative prices of factors change, the proportion in which they are employed will change as well, in order to reestablish equality between marginal product and input prices. This is known as the principle of variation. With respect to labor ($p$ and $w$ are, respectively, the unit prices of output and labor), profit maximization requires that, at equilibrium, the real wage should be equal to MPL: $\frac{\Delta y}{\Delta l} = w/p$. This can also be written as $p \frac{\Delta y}{\Delta l} = w$ (the second order condition for a maximum is guaranteed by the assumption that MPL is, at least to a certain level of $l$, on, a decreasing function of $l$). The equation $p \frac{\Delta y}{\Delta l}$ represents the value of the marginal product of labor (VMP) and its schedule below the maximum of the value of average product of labor (VAPL). $VMP = \frac{p \Delta y}{\Delta l}$ represents the short-run firm’s demand curve for labor. If the firm operates in a noncompetitive market for its product, profit maximization requires that $MPL \times MR = w$, where MR is the marginal revenue generated by an extra unit of output (in perfect competition $MR = p$). $MPL \times MR$ is called the marginal revenue product, and in this case its schedule (below the maximum of VAPL) represents the short-run firm’s demand curve for labor (a deeper analysis of these matters may be found in any standard microeconomic text).

THE LAW OF VARIABLE PROPORTIONS AND THE LAW OF DIMINISHING PRODUCT

Consider, for the sake of simplicity, a “canonical” short-run production function: $y = f(K_0, l) = F(l)$, where $l$ (as before) is labor, $y$ is the output of the firm, and $K_0$ is a fixed given amount of another input that is conventionally defined as “capital” (or better services of a “capital
good”). Neoclassical production theory admits various possibilities concerning the variation of MPL as \( l \) changes. According to the law of variable proportions, as the firm increases the use of labor, holding \( K \) constant at a given level \( (K_0) \), the output will first increase at an increasing rate up to a point, say \( l = l^* \), and thereafter increase at a decreasing rate, depicting a S-shaped production function. This law expresses the idea that, for given input prices, there is an optimal employment ratio of \( K \) and \( l \) in correspondence of each quantity of output produced, but since capital is an indivisible input the firm cannot use less capital than \( K_0 \). Consequently, the first increments of \( l \) will cause \( y \) to increase at an increasing rate, since the addition of further units of labor leads to a more “favorable” proportion between \( l \) and \( K_0 \). However, successive additions of labor will lead, sooner or later, to a point (\( E \) in Fig. 1) where the constraint of the constant factor will operate in the opposite manner. From this point on, further units of labor lead to a less “favorable” proportion between \( l \) and \( K_0 \), so that each additional unit of labor will add less output than its predecessors.

Another widely used assumption about MPL is the so-called law of diminishing product, which states that as \( l \) increases, output will always increase less than proportionately, implying a concave production function (the explanation is the same as for the one given above from point \( E \) on). Although this second law avoids the indivisibility assumption (which is not necessary in the neoclassical productivity theory, and may lead to some theoretical contradictions), it rests on an idea that is sometimes difficult to justify: that MPL will always decrease whatever the given amount of \( K \) may be.

Both laws admit the possibility that a level of \( l \) may be reached at which MPL = 0, after which further increments of \( l \) will cause the MPL to become negative. One could say that at this point the given capital stock will treat further additions of labor as a “disservice.”

**HISTORICAL DEVELOPMENT OF THE CONCEPT**

The first formulation of the law of variable proportions can be found in a work by the French economist Anne-Robert-Jacques Turgot (1727–1781), who showed that when advances (seeds) on a given piece of land are increased, the product will first rise more than proportionately, but that after a certain point the diminishing product will prevail, until “the fertility of the soil being exhausted … an addition to the advances will add nothing whatever to the produce” (quoted in Sraffa 1925, pp. 327–328). The role of MPL in the explanation of labor’s reward may be found in various forerunners of marginal revolution, and in the works of the earlier neoclassical economists—particularly William Stanly Jevons (1835–1882) and Carl Menger (1840–1921). Only in the 1890s, however, with the contributions of John Bates Clark, Alfred Marshall, Knut Wicksell, and Philip H. Wicksteed, was a coherent theory of distribution fully established. Marshall, also through numerical examples, proved that profit maximization requires that real wages equal MLP. Clark claimed that, according to the marginal theory, production and distribution become faces of the same process of determination of value (undoubtedly one of the main goals of neoclassical theory), and that each “social class gets what it contributes, under natural law, to the general output of industry” (Clark 1891, p. 313; see also Clark 1899, p. v).

A few years later, however, Wicksteed showed that the marginal theory of distribution, in order to be consistent, must assume a homogeneous production function of degree 1 (i.e., constant returns to scale). Only under this assumption, in fact, would the sum of factors’ rewards, determined on the basis of their marginal products, be equal to the total output produced (this is the product exhaustion theorem). The assumptions about production processes and the “laws” governing income distribution thus became strictly interconnected, requiring the marginal theory of distribution, if it is to be consistent, to postulate a particular configuration of productive processes. Wicksell thus suggested using the following production function (later called Cobb-Douglas): \( y = l^\alpha K^\beta \), with \( \alpha > 0 \), \( \beta > 0 \), \( \alpha + \beta = 1 \). This function, and the law of diminishing product of labor (and

**Labor, Marginal Product of**
of capital) it incorporates, is still the most commonly used in neoclassical micro- and macroeconomic theory. It should be noted that the assumption of constant returns to scale represents a serious limitation, since it rules out the important phenomenon of increasing returns to scale—that is, it rules out the case for: $\alpha + \beta > 1$ (see Debreu 1959, p. 41, for a similar statement with regard to general economic equilibrium analysis).

**SOME CRITICISMS**

Soon after its formulation, the neoclassical theory of wages raised many “grumbles,” as Dennis Robertson put it. One criticism concerned the distributive justice implied by what Clark defined as “natural law.” It was pointed out that only the last—or better, the “marginal”—worker would be paid according to his or her contribution to production (equal to the marginal product), while all the other workers would be paid less than that, because under the assumption of diminishing product of labor, their marginal product is higher than that of the last worker employed. The marginal theory of distribution would therefore imply labor “exploitation.”

Two points should be noted here. First, it makes sense to talk of a “first worker,” a “second worker,” and so on, only in a logical sense, since labor $l$ is a homogeneous factor of production, and all that can really be discussed is the marginal product of the homogeneous factor $l$ (Clark 1891, p. 308). Second, the “exploitation” (of both labor and other inputs) is denied by the assumption (fully compatible with other hypothesis about MPL) of constant returns to scale, which guarantees product exhaustion.

Contrary to Clark’s claim, however, even if labor is considered a homogeneous factor, empirical evidence suggests that discrimination on labor markets may lead to wage differentials for equally productive worker groups. Beginning with the seminal work of Gary Becker in 1957, neoclassical theory has explained discrimination mainly as the outcome of personal prejudices of some groups (particularly employers) against others (women, racial minorities, etc.). Suppose that an employer (in a competitive product market) has a prejudice against a group, say women (although females and males have, by assumption, the same marginal productivity). On the basis of this prejudice, the employer will undervalue women’s contribution to production, with the consequence that different equilibrium wages for the two groups will be fixed. The monetary wages of females and males are represented by $w_f$ and $w_m$, respectively, so that labor market equilibrium conditions are given by for males, and by for females, where $d > 0$ is the “discrimination coefficient” that measures the employer’s prejudice. Since MPL is the same for both men and women, it is easy to realize that women will be paid less than their VMPL (i.e., $w_f = w_m - d$). According to this model, discrimination is possible only in the short run, however, since competition among employers and workers will eventually equalize the wages of the two groups.

Alternative non-neoclassical models explain the persistence of discrimination by focusing on the “segmented labor market approach,” in a general noncompetitive theoretical framework. According to this approach, if the labor market is split into submarkets (think of the “dual” labor-market case, with a “primary” and a “secondary” segment), and if there are barriers to employee mobility, discrimination may take the form of occupational segregation, since workers who are discriminated against will be crowded into the only accessible labor market characterized by a lower equilibrium wage. In this case, however, unlike the neoclassical “taste model” presented above, all workers are paid according to their actual VMPL and wage differentials are the result of different labor supply conditions in the two submarkets, given the presence of barriers to employee mobility (see Smith 2003, ch. 6 and Ehrenberg-Smith 2003, ch. 12, for an exhaustive overview of discrimination theories).

Other criticisms concentrate on the “impossibility of disentangling the specific product of the various factors of production, even at the margin of their application” (Robertson 1931, p. 224). This argument rejects the very possibility of defining and measuring the marginal product of a factor (and particularly of labor). Among the various authors who have raised objections of this kind is J. A. Hobson, who did a good job synthesizing the various implications of the argument. In his view, if a productive process is characterized by cooperating factors employed in a well-defined proportion, an increase or a reduction of one of these factors (e.g., labor) will imply a reorganization of the entire process, thus modifying the average and marginal product of all the other fixed factors. If this is the case, it is not possible to attribute the corresponding change in output to one variable factor alone. Marshall, following Francis Y. Edgeworth, claimed that Hobson mistakenly assumed a discrete “violent check” in the supply of one input, rather than referring to continuous variations at the margin. In this case, the changes in the marginal product of the fixed factors would be negligible. In other words, Hobson’s critics maintain that he was wrong because he was referring to a “broad” variation, while rigorously marginal productivity theory is concerned with the infinitesimal variation. Here, the relevance of the distinction between the marginal product and the marginal productivity of labor becomes apparent.

Hobson, however, was clearly discussing quite a different problem, which can be explained in the following
way: If inputs used in a productive process must be employed in a well-defined fixed proportion, the principle of variation is not effective, and consequently the marginal product of labor (or of any other input) is a meaningless concept. An increase in one unit of labor will probably yield no additional output, while the withdrawal of one unit of labor will cause a notable diminution of both total product and the contribution of other inputs. In other words, if capital has to be considered as a specified physical endowment of goods, it could be combined only with a specified amount of labor (unless it is a sort of “butter capital” or “jelly capital,” as John B. Clark put it, that can employ a widely variable quantity of labor). This position is still supported by many opponents to neoclassical theory, and it was partially supported by some of the older neoclassical economists, such as Léon Walras and Vilfredo Pareto.

There is a less radical way to consider Hobson’s criticism. Although an extra unit of labor may cause an increase in total output, this can only occur if the productive process is reorganized by way of a change in technique of production, such as an increase in the division of labor. But this means that one is not working on the same production function, but rather “jumping” from one function to another one. In this case, there would be little sense in talking about the marginal product of labor in a static framework. The idea of a change in the technological configuration as the employment of labor is changed is a characteristic feature of modern theory of economic growth and particularly of the literature on increasing returns (a line of thought of this kind can be traced back to Adam Smith, passing through Allyn A. Young up to the contributions in the late 1990s of James Buchanan and Yong J. Yoon with their notion of “generalized increasing returns”).

Hobson’s criticism anticipated most of the elements later discussed in the famous “Cambridge Capital Controversies” that raged from the mid-1950s to the mid-1970s between neoclassical economists in Cambridge, Massachusetts, and post-Keynesian economists in Cambridge, United Kingdom. Although the controversy was mainly concerned with the nature and the unit of measure of capital, it nevertheless had serious implications for the consistency of the whole marginal theory of distribution. In fact, the main theoretical result of the debate was that if one considers a production process that employs (given the assumption of constant returns to scale) at least one other factor of production in addition to labor (i.e., “capital”), then, in general, it will be impossible to derive distributive shares from the specification of production function. Furthermore, the critics pointed out that, in general, other “strange” phenomena—such as “capital inversion” or the “re-switching of techniques”—may occur, which would undermine the principle of variation.

In conclusion, the only case consistent with the marginal productivity theory is that of a “one-commodity” economy, in which capital (in line with Clark’s definition) is indistinguishable from consumption goods, and in which the only specific input is represented by labor. But in this case, as the critics have pointed out, both Ricardian and Marxian theories of value and distribution hold.

LABOR, SURPLUS: CONVENTIONAL ECONOMICS

Surplus labor models are a class of models for analyzing developing countries as dual economies with a modern capitalist sector and a traditional precapitalist sector. The precapitalist sector is viewed as having a large pool (“unlimited supplies”) of labor from which the capitalist sector may draw at constant cost. While these models are often described as finding their inspiration in the old classical economists and Karl Marx, the 1954 model of W. Arthur Lewis and its extensions are technically more neoclassical than truly classical. The Lewis model was elaborated and formalized by many others, most notably John C. H. Fei and Gustav Ranis (1964), with important theoretical contributions from Amartya Sen (1966) and Stephen Marglin (1976). Questions have been raised as to the historical relevance of the neoclassical labor surplus models (Schultz 1964; Myint 1971; Arrighi 1973; Williamson 1985).

In the Lewis model, the economy is divided into two sectors, a traditional precapitalist sector and a modern capitalist sector. Lewis emphasized that this sectoral distinction is not identical to that between manufacturing and agriculture, as there may be both traditional (craft) manufactures and capitalist agriculture. The traditional sector is characterized by a large pool of labor, available to the modern sector at a constant (subsistence) wage. The wage is exogenous and above the marginal product of labor in the traditional sector. Thus the labor supply in the modern sector is infinitely elastic. Lewis stated that the marginal product of labor in the traditional sector could be small, zero, or even negative, but whereas he also emphasized that this was not an assumption of fundamental importance, later developers and critics of the model devoted considerable attention to this assumption. For Lewis, the supply of labor is considered “unlimited” as long as the labor supply exceeds labor demand at the subsistence wage rate. The demand for labor in the modern sector is determined by the stock of capital. Under such conditions, labor shortage is never a constraint on the expansion of the modern sector. As demand is also not a constraint on expansion in the Lewis model, the modern sector hires labor out of the traditional sector, and output increases. Profits in the modern sector rise and are reinvested, fueling capital accumulation. This is how successful “development” is defined. Eventually, the marginal product of labor and the wage will become equal in both the traditional and modern sector, and dualism comes to an end. With the equalization of the wage in the two sectors, the presumption is that the wage will now be “neoclassically” (i.e., “market”) determined.

A number of criticisms have been made of the Lewis model (see, for example, Leeson 1979; Bharadwaj 1979). First, it has been argued that the model assumes that employment transfer proceeds at the same rate as capital accumulation in the modern sector, and that this will not be the case if there is laborsaving technological change in that sector. Lewis did recognize that there are two forces working in opposite directions—capital accumulation increasing employment and technical advance which may reduce employment—though he rejected the argument that the latter would outweigh the former on empirical grounds in his original article. Second, a number of critics have asserted that the situation in many developing countries is precisely the opposite of what Lewis assumed: There is significant unemployment and underemployment in urban areas and full employment in rural areas. A defense of Lewis might point out that the traditional/modern distinction is not the same as the rural/urban distinction, and that what appears as full employment in some areas is disguised unemployment; people are working, but their transfer from the traditional to the modern sector will not reduce output in the traditional sector, or will only reduce output there by the amount that the individual was consuming. Third, it has been noted that Lewis assumes away the problem of the creation of a capitalist or entrepreneurial class in developing countries, whereas in fact this is one of the main obstacles to development. Fourth, critics have argued that real and nominal wages in the modern sector do not appear to behave in the way they are pictured in the Lewis model—they both are able to rise quite rapidly—and the relation of wages and employment also differs in that rates rise even in an atmosphere of significant unemployment. Fifth, Lewis's
assumption that the sectors are homogeneous has been criticized with arguments developed that each sector can be quite heterogeneous, generating conflicts that affect the accumulation process. Finally, the assumption that “perfect competition” holds in the capitalist sector has been attacked both for ignoring the way in which monopoly characteristics had been inherited from the colonial era and for the neoclassical implications for the analysis of investment, allocation, and factor payments.

The Lewis model has also been criticized on historical grounds. Jeffrey Williamson (1985) argues that the early British experience does not confirm the model, while Giovanni Arrighi (1973) has attacked the argument that the model applies to southern Africa. One of the primary challenges of colonial capitalism was getting the indigenous populations to work as wage laborers or grow cash crops when they still had possession of means of production for producing the means of subsistence. In addition to forced labor and land alienation, the requirement that taxes be paid in colonial currency was one of the most important means of pressuring Africans to work on plantations and in mines or to grow cash crops.

Others challenging Lewis concerning surplus labor in developing nations included Theodore Schultz (1964) and Hla Myint (1971). Schultz studied the 1918–1919 influenza epidemic in India and the changes in output resulting from the reduction of the labor force, concluding that the surplus labor theory is false. Sen (1967) replied that the surplus labor doctrine refers to changes in the labor force resulting from the operation of economic incentives and principles, and that the influenza epidemic does not qualify. A single family member leaving the traditional sector is not the same as an entire family dying from influenza. Myint (1971) critiqued the idea that if a family member leaves a traditional farm, the other family members will increase their labor services to maintain a target level of output. Many of these critiques confuse modern/traditional with manufacturing/agriculture and, moreover, continue to ignore Lewis’s claim that the assumption of zero marginal productivity is not crucial, that the marginal product of labor can be zero, positive, or negative, and that the supply of labor is considered “unlimited” as long as the labor supply exceeds labor demand at the subsistence wage rate.

LABOR, SURPLUS: MARXIST AND RADICAL ECONOMICS

The theory of capitalist accumulation devised by Karl Marx (1818–1883) rests upon the labor theory of value, according to which capitalists (i.e., owners of the means of production) appropriate the surplus value produced by the workers (i.e., owners of labor power or the capacity to labor) whose labor power they purchase. Capitalists then sell the products in which surplus value is embodied, and keep the profits for themselves. If, after commodities are sold, capitalists were to end up with an amount of capital equal to that spent purchasing the elements of the production process—that is, without profits—they would not invest. Investments are profitable, however, because the product can be sold for a sum greater than the original investment. In the production process, workers produce not only value but surplus value—that is, value greater than the value of their labor power; it is the sale of surplus value that is the source of profits. The value of the means of production is incorporated, unchanged, in the product, as machines and tools wear out and are eventually replaced by others. The difference between the value of labor power (i.e., the amount capitalists spend in wages)

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 309
Labor, Surplus: Marxist and Radical Economics

and the value labor power produces in the production process (i.e., the amount capitalists collect once the product is sold) is the profit capitalists appropriate. To understand why this is so, it is necessary to examine the main features of the capitalist production process.

Labour power, under capitalism, is a commodity that has the property of producing value. The value of labour power, like the value of any other commodity, is determined by the labour time necessary for its production and reproduction. As labour power is a capacity of living workers, its value is resolved in the labour time necessary for the production of the means of subsistence (i.e., a historically established bundle of commodities) necessary for the maintenance, and reproduction over time, of the individuals whose livelihood depends on their ability to sell their labour power in exchange for wages (Marx [1867] 1967, pp. 169–171). The use-value of labour power is its exercise in the production process where, combined with means of production and various materials, it produces specific useful goods, or use-values. Capitalists purchase the elements of the production process: means of production, raw materials or already processed materials, and labour power. They consume the use-value of labour power by setting the workers to work. Capitalists control the labour process and own its products, a quantity of use-values which, when sold, become commodities imbued with value and exchange-value (Marx [1867] 1967, pp. 174–175).

Workers sell their labour power for wages sufficient for the sustenance of themselves and, to a variable extent, their families. Once sold, the use-value of their labour power belongs to the capitalist who, being in control of the production process, can fix the length of the working day within limits set by the outcome of struggles between the capitalist class and the working class (Marx [1867] 1967, p. 235; Weeks 1981, p. 69). The working day can be divided in two parts of varying duration. During a number of hours that depends on the quantity of labour time necessary to produce the workers’ means of subsistence, workers produce a value equivalent to their wages. In this portion of the working day, workers engage in necessary labor, which is spent in necessary labour time. It is necessary because workers need to replenish their energies and because capitalists need a productive labor force. The working day, however, lasts longer than the time necessary to produce the value of the wages. Workers are compelled to engage in surplus labor, creating value for the capitalist during surplus labor time. Capitalists seek to lengthen the quantity of surplus labor time by keeping wages low, thus decreasing the quantity of necessary labor time. The lower the value of the commodities necessary to maintain and reproduce labor power, the lower the wages and the higher the quantity of surplus labor time. The ratio of surplus labor to necessary labor, which can also be stated as the ratio of the surplus value to the value of the wages or variable capital, is the rate of surplus value that “expresses the degree of exploitation of labor-power by capital, or of the laborer by the capitalist” (Marx [1867] 1967, pp. 216–218). The higher the rate of exploitation, the greater the profits and the power of the owners, who constantly strive to increase the rate of exploitation by lengthening the working day or by introducing technology intended to speed up the production process or replace workers with machines.

In the processes of capital accumulation, the proportion of capital invested in means of production (i.e., constant capital) and labour power (i.e., variable capital) can remain constant or it can change. If it remains constant, the more capital is invested, the greater the demand for laborers; as technology remains the same, the rate of exploitation remains unchanged. Growth in the demand for labor can lead to higher wages as long as profits are not diminished. When wages rise to the extent of undermining profits, capitalists may choose to slow down investments, thus producing a decline in employment and wages, or they may force workers to labor longer hours, thus lengthening the proportion of the working day spent in surplus labor. With the development of the forces of production (i.e., technological changes increasing the productivity of labor), it becomes possible for capitalists to augment their profits while reducing, at the same time, the demand for labor: more capital is invested in constant capital and less is spent in wages or variable capital. The greater the productivity of labor, the lower the quantity of labor time spent in necessary labor, the greater the proportion of the working day spent in surplus labor, and, therefore, the greater the profits.

Technological changes and growth in the productivity of labor result in changes in the division of labor and in the quantity and quality of the demand for labor. Changes in the division of labor increasing the demand for more skilled labor result in higher wages for those fortunate enough to have those skills, or access to the necessary training to acquire such skills. At the same time, these changes devalue formerly needed skills and push masses of workers into underemployment and unemployment. The relatively privileged position of skilled workers, however, is not permanent, as capitalists seek to lower wages through processes of de-skilling (i.e., breaking up skilled jobs into their constituent elements) even as they develop new technologies that eventually will render such jobs obsolete, in a never-ending cycle of skilling and deskilling that exploits and discards workers as mere things to be used as needed in the process of capital accumulation (Braverman 1974).

Quantitative changes in the demand for labor reflect changes in the composition of total capital invested; that is, in the proportion of capital invested in constant and
variable capital. As capital investment and the productivity of labor increase, the demand for labor decreases relative to the quantity of capital invested (Marx [1867] 1967, p. 629). These changes in the composition of capital are reflected in fluctuations in the employment rate and growth in unemployment. It would seem that there are too many workers, that the labor force is increasing too fast, that workers are having too many children, and so on. But, as Marx observed, this apparent increase in the size of the laboring population is an illusion: “it is capitalistic accumulation itself that constantly produces … a relatively redundant population of laborers … a surplus population” (Marx [1867] 1967, p. 630). As capitalists use increasingly productive technology (e.g., assembly lines, automation), less and less labor time is needed to produce larger quantities of products and a growing proportion of workers become unemployed and even unemployable, thus constituting a “reserve army of labor” or relative surplus population (RSP), which has important economic and political effects: its presence limits the bargaining power of workers even at times of economic growth.

Within a national economy, the RSP can assume three forms: (1) the floating RSP, which is manifested when rapid and drastic technological changes substantially alter the location and kind of capital investments and the organization of production, thus producing rapid declines in employment; (2) the latent RSP, which emerges in rural areas as agribusiness replaces small, labor-intensive farming and farmworkers migrate to the urban and industrial areas; and (3) the stagnant RSP, which includes masses of workers permanently expelled from the labor force, able to obtain only irregular employment but remaining largely unemployed, constituting a large reserve of very low-paid, low-skilled, and unskilled labor power (e.g., today’s poverty and near poverty population in the United States, largely dependent on welfare and irregular, minimum-wage employment). The stagnant RSP becomes “a self-reproducing and self-perpetuating element of the working class, taking a proportionally greater part in the general increase of that class than the other elements” (Marx, [1867] 1967, p. 640).

SURPLUS LABOR AND SOCIAL CLASS

Exploitation is “a social (society-wide) phenomenon under capitalism” (Weeks 1981, p. 64); it is at the core of the Marxist concept of social class, as an exploitative relation between capitalists and workers. While this seems a clear and useful definition, changes in the forces of production since the mid-nineteenth century have produced qualitative changes in the social and technical divisions of labor, thus altering the composition of the working population. In advanced capitalist social formations, like the United States, the proportion of workers exploited at the point of production, producing surplus labor for the owners of capital, has declined relative to the proportion of workers employed in services, white-collar, technical, professional, and managerial jobs. Automation and information technologies have contributed to the decline in the proportion of well-paid blue-collar workers that, in the United States, were considered “the backbone of the middle class.”

Were Marxist social scientists to define the working class using as the sole criteria the production of surplus labor by manual workers, they would have to conclude that the size of this class is dwindling. The Marxist theorist Nicos Poulantzas (1936–1979), for example, argued that only productive workers (i.e., workers who produce surplus value) are part of the working class, unlike unproductive workers, whose work is located in the other spheres of the mode of production (e.g., circulation). Not all productive workers, however, are members of the working class; technicians and engineers, for example, occupy a contradictory class position, for they contribute to the production of surplus value while placed in positions of authority over the labor process, thus representing the power of capital. Classes cannot be identified solely on economic criteria; ideological and political criteria—namely, location in the relations of production and the social division of labor—matter as well (Poulantzas 1973, pp. 31–35).

GLOBALIZATION, SURPLUS LABOR, AND CLASS

When examining classes empirically, at the level of social formations, the capitalist/working class dichotomy is submerged under the heterogeneity of the technical and social division of labor, and the existence of noncapitalist classes, such as the petty bourgeoisie (independent producers) and the peasantry. Social scientists are compelled to introduce additional criteria for defining classes, such as, for example, contradictory class locations based on property relations, levels of skills and knowledge, and location in authority relations (e.g., Wright 1997). The heterogeneity of the working population does not obliterate, however, the importance of the underlying division between capitalists and workers and the significance of surplus labor in the process of capital accumulation. As capitalists seek to increase profits and lower labor costs, they continuously revolutionize the organization of production and change the kind and location of investments. Capitalist accumulation strategies result in changes in the quantity and quality of the demand for labor, changes in the social and technical division of labor, and, consequently, changes in the social stratification profile that can be documented in
a given society at a given time. These changes reflect not only technological imperatives and competition among capitalists, but the extent of capitalist power over the working classes.

In the United States, where labor is relatively powerless if compared with its counterpart in Western Europe, globalization has resulted in declining benefits and real wages for the working classes; a decline in job security, benefits, and employment opportunities for the middle classes; and deepening wealth and income inequality. Downsizing, outsourcing, deindustrialization, growth in poorly paid service jobs, temporary and contingent employment, and, consequently, growth in the size of all the forms of the RSPs, especially the stagnant RSP, are some of the effects of capitalist efforts to lower labor costs. The value of labor power in poorer countries is very low, thus resulting in a higher rate of exploitation; capitalists seeking higher profits flock to those countries, intensifying inequality and the growth of their RSPs, thus triggering massive migration flows toward the wealthy countries. The working classes in the wealthy capitalist countries, therefore, face national and global RSPs that have effectively contributed to the undermining of workers’ bargaining power. Contributing to the lowering of the value of labor power in the rich countries is the export of cheap commodities from China and other exceedingly low-wage countries, which thus lowers the overall cost of the bundle of commodities necessary for the maintenance and reproduction of the working population.

To conclude, at the level of analysis of social formations, surplus labor plays a lesser role in the identification of social classes. However, at the level of analysis of the capitalist mode of production, globally considered or within a country, it is not possible to understand changes in the empirically observable stratification system without taking into account the dynamics of class exploitation and capital accumulation, which, as capitalists pursue the appropriation of as much surplus labor as feasible, constantly alter the structure of opportunities of all working people.

**LABOR DEMAND**

The “demand for labor” is usually understood by economists to mean the demand for labor services by a firm, an industry, or the economy at a given real wage. In a capitalist economy, labor becomes a commodity that is bought and sold on the market just like any other commodity, such as bread or butter. Labor is a unique commodity, however, and when an employer buys labor, he or she obtains a worker’s “labor power” which is the amount of services that the employer gets from the worker. These services depend on the power the employer has over the worker. If there is high unemployment, for example, the worker is in a weak position and greater labor services can be extracted from him or her. The amount of labor services that the employer obtains (not only in terms of hours of work, but in terms of the efficiency of those services) also depends on the nature of the employment contract, the real wage paid to the worker, the conditions of employment, and the attitude of the employer to the worker (and vice versa).

Labor services consist of three components: the number of workers (employees), the average hours worked per worker, and the efficiency per hour of the worker. There are several institutional and legal constraints on employers in most developed countries. For example, there may be laws against discrimination, equal pay legislation, minimum wages (henceforth, the term wages refer to real wages), occupational health and safety requirements, hiring and firing restrictions, and penalty rates for overtime.

The demand for labor is a derived demand: Firms wish to hire workers to produce goods and services that they sell in order to earn profits. Alfred Marshall, in his *Principles of Economics* (1930) suggested that labor demand becomes more responsive to wage changes if the substitution possibilities between labor and capital increase. In other words, the easier it is to substitute capital for labor, the greater the share of wages in total costs, and the more responsive the other factors of production are to their prices.
Much of the formal economics literature is based on simple models of firm behavior in a perfectly competitive economy (for a closed economy, that is, without any international trade), assuming that labor is a homogeneous commodity. In a prototype model, a firm is assumed to maximize profits (or minimize costs) subject to a so-called “well-behaved” production function that depends on homogeneous labor and capital. By simple mathematical manipulation, it is easy to show that the firm’s demand for labor is a negatively sloped marginal revenue product (MRP) curve, and that employment is determined by equating the marginal revenue product of labor with the wage rate. In such models, it is usually assumed that labor and capital are substitutable (usually in a Cobb-Douglas production function). There are some difficulties, however, in moving from a firm labor-demand function to an industry or aggregate labor-demand function because of the possible interactions between firms, the heterogeneity of labor, and other factors.

In most of these models, it is assumed that the technology of production is given and unchanging. Alternatively, technological change is simply an exogenous variable that falls like manna from heaven on all existing inputs. Labor services are often assumed to be such that hours of work and employees are perfectly substitutable.

The impact of technological change on the labor market and on labor mobility is very significant, but it often has contradictory effects. Technological change is usually defined as being either a change in the product or a change in the process of production. Technological change that leads to the introduction of new products will lead to either new firms being set up or old firms expanding into a new product line, which would lead to increased employment through job creation and job destruction. Job destruction leads to the closing down of firms producing some products that are replaced by new firms producing new products. However, demand for a new product may lessen demand for competing products, leading to a reduction in labor demand elsewhere in the economy. Similarly, a technological change in the production process may lead to the substitution of capital for unskilled labor, and hence to a decrease in labor demand. It may also lead to an increase in the demand for skilled labor, however, due to a complementarity of capital with skilled labor.

In more advanced models, labor is treated as a “quasi-fixed” input, like a capital good (see Oi 1962; Nickell 1986). In other words, there are significant fixed costs associated with changing employment, due to hiring and firing costs. Usually, it is assumed that these costs of adjustment are quadratic (implying increasing marginal costs of adjustment), so that if there is an increase in the demand for goods the impact on the demand for labor is spread out over a few periods. In the short run, the demand for labor adjusts slowly in response to any external shock. Given that there are costs of adjustment, the firm would find it easier to either adjust the hours of work of existing workers or hire casual part-time workers. It is cheaper, however, to hire and fire casual part-time workers. European countries that have a more regulated labor market, with larger hiring and firing costs, have been found to have a slower adjustment process to shocks. However, the evidence on this is very controversial and needs further research (see Blanchard 2006).

There has been a large amount of econometric work to estimate the impact of a change in real wage rates (corrected for inflation) on labor demand holding the level of production constant using large datasets. Most of these studies have found that elasticity (the percentage change in labor demand in response to a 1 percent change in the real wage rate) lies between –0.15 and –0.75, with “a best guess” of –0.30. However, studies of the impact of minimum wages on employment suggest that there is no significant impact (see Card and Krueger 1995). David Neumark and William Wascher have found otherwise, however, perhaps because it is mainly unskilled labor, while usual studies of labor demand are for skilled and unskilled labor taken as a whole. The scale elasticity (i.e., the impact of increased output) is almost unity: a 1 percent increase in the level of production (output) leads to a 1 percent increase in labor demand.

Firms demand labor services from employees who provide honest, committed, and productive work at wage rates that the employer determines (either unilaterally or as a bargain between the employer and employee). Ideally, employers would like to employ workers who take a positive long-term interest in their work and make useful suggestions to improve the production process. In general, firms have flexibility in the wage (and other conditions of work, including perquisites) they offer to their employees. There are also theories of deferred payment, tournaments to provide a stimulus to get wage increases, and “efficiency wages.” It has been shown that employers can get higher productivity from their workers, and hence make higher profits, if they pay a higher real wage. This idea was first put forward in a classic paper by Harvey Leibenstein (1957), who argued that in a developing country, paying higher wages led to workers getting better nutrition and providing better productivity.

This essential link between wages and productivity, or “efficiency wages,” was extended in a series of papers: In 1984, Carl Shapiro and Joseph Stiglitz put forward the view that higher wages decreased shirking by employees; Steven Salop argued in 1979 that higher wages lowered worker turnover, increased productivity, and increased profits; and Andrew Weiss (in 1980) and George Akerlof...
(in 1982) both showed that if employers paid higher wages as a partial gift, workers would reciprocate by providing greater effort. Thus, there is no unique negative relationship between the real wage and employment, because an employer who pays a wage in excess of the “market wage” gets greater productivity. Lowering the wage does not increase employment. Experimental economics, particularly the work of Ernst Fehr and Simon Gächter, has shown the importance of considerations of “reciprocity” (e.g., fairness, equity, and other issues) in the employment relationship.

In a globalized world, the demand for labor becomes more confused as various activities are “outsourced.” In other words, the firm can produce a larger quantity of output by either hiring more labor, buying more capital goods, improving its technology, or simply by outsourcing a particular activity. Call centers in less developed countries are good examples of this. Hence, the link between the output of a firm and its demand for labor is no longer constrained by a given production function.

There has been a large amount of econometric analyses of the demand for labor, suggesting, in general, a negative link between wages and employment. There are important policy implications that can flow from the research about minimum wages, but the results are contradictory and controversial (see Card and Krueger 1995; Neumark and Wascher 1992). Similarly, the efficiency wage literature also throws some doubt on a simple negative relation between wages and employment. The literature on hiring and firing costs has been used to suggest that a deregulated labor market would lead to higher employment, but this is still being debated.

LABOR FORCE PARTICIPATION

The labor force participation rate is defined as the proportion of a population that is either employed for pay or profit (for one hour or more in the reference week or four weeks) or looking for paid work over some period of time. By definition, people who are carrying out unpaid work in the home or voluntary work are not counted as employed.

The concepts of employment and unemployment are more easily defined for a developed capitalist economy that has a market for wage labor. In less developed countries (LDCs), where wage labor is not a predominant form of employment, the concept of unemployment becomes “fuzzy”: ‘The line between employment in the informal sector (e.g., selling cigarettes on street corners) and unemployment is not clearly defined (see Turnham 1993). Similarly, the concept of “looking for work” becomes vague when social security benefits are not available and
when labor markets are not developed. Often, when the unemployed are unable to find work for any length of time they give up looking for work and hence are not in the labor force (they are the so-called “discouraged workers”). In societies that provide welfare benefits to people with disabilities, people often move between the unemployed and disabled categories, and hence the participation rate as measured is unclear. Because the concept of unemployment is problematic in some countries, economists often compare employment-population ratios instead of participation rates.

Social customs, culture, and institutions (including the legal framework) play a large part in the participation of women and younger people in the labor market. In LDCs where there is no compulsory schooling, children are part of the labor force. In certain cultures where religion plays an important role, females do not engage in paid work and hence are not part of the labor force.

It is common to distinguish between the participation rate of males and females, and more detailed studies look at differences in the participation rates of several subgroups, such as married females and single females, whites and blacks, young and old, migrants and natives. In general, female labor force participation rates have been rising and male participation rates have been falling in most countries of the Organization for Economic Cooperation and Development (OECD), except for Japan, where male participation rates have risen. Male participation rates for older workers have been rising since the mid-1990s, possibly because of better employment conditions and better superannuation provisions for retirement after sixty-five years of age, or due to (in the United States) provision of health care for employed workers. Note, however, that the participation rate of both males and females has fallen in the United States since 2000, and whether this is a trend fall or a cyclical fall is a contentious issue (see Aaronson et al. 2006 and Juhn and Potter 2006). Participation rates tend to first rise with age and then fall as people get older. Participation rates of more educated people are usually higher than those of less educated people.

During World War II many women from the combatant countries worked in the war industries, and after the end of the war continued in the labor force. The increase in female participation rate is sometimes explained by the change in the structure of the economy from a dominant manufacturing sector to a dominant services sector that demands (allegedly) “feminine” skills such as computer keyboard skills. The increased level of education of females has also led to increased female participation, especially in white-collar jobs, often in part-time employment. The changing social mores that came with the women’s liberation movement and the increased access to and ease of contraception via the Pill, which provided greater control over and timing of childbearing, lowered fertility rates and increased female participation rates. Increased real wages of women, as well as the introduction of equal pay legislation in many OECD countries, increased female participation rates. The development of household appliances (e.g., washing machines, microwave ovens, and so on) that lower time spent in household work for females have also had a positive impact on female participation rates (see Blau and Ferber 1992).

Male participation rates have declined with a fall in employment in the manufacturing sector, especially for older males who were made redundant and were unable to find work in the newer industries. However, in most OECD countries expanding economies (and perhaps the tightening of access to welfare benefits) appear to have increased participation rates for all males (including older males) since about 2000.

It is important to note that the labor force participation rate depends on both demand and supply factors: For example, a higher proportion of women are working if the demand for the skills that women offer is high. Generally, participation rates are procyclical: They rise during booms and fall in recessions. If for some reason employers discriminate against women in one country, their participation rate is lower than in a society where such discrimination does not exist. Similarly, women’s participation rate is higher when they place a lower value on their time spent at home, and so are willing to supply more labor.

Economic analysis of labor force participation begins with neoclassical models of utility maximization subject to a budget constraint: Individuals are assumed to be maximizing their individual welfare (dependent on consumption and leisure or nonmarket time) subject to a given wage rate and some nonlabor income (either from social security or from family sources). (Usually the models are based on individual maximization, rather than family decision-making.) This typically provides an individual with a “reservation wage” that depends on the value of leisure (or nonmarket time). A “reservation wage” is defined as that wage below which the individual prefers not to work. Individuals have different reservation wages depending on their preferences for leisure, their access to nonlabor incomes, and their educational background. Female labor force participation is more difficult to analyze due to their roles as household managers, childbearers and caretakers, and paid market work. Even though social mores have changed over the past few decades, women continue to do the same amount of unpaid household work.

Models that allow for family decision-making (where the husband and wife choose whether to work or not, and
decide who produces “household goods,” e.g., child care at home, meals at home, etc.) are more complex and difficult to estimate econometrically. Some models treat these as “bargaining models” in a game theoretic context. In general, the probability of a wife working is positively related to her husband working (Pencavel 1998). This may, of course, also be explained in terms of “assortative mating”—that is, highly educated and well paid males tend to marry highly educated and well paid females.

In a life-cycle context, males invest in education in their youth, then work and acquire pension or superannuation benefits, and retire in older age. Females invest in education (more so since World War II), work for some time, have children and leave the labor force, return to the labor force when the children are of school-leaving age, and then work until retirement. This stylized life-cycle behavior is easily explained by simple models of utility maximization. Participation rates of young people decreased with the increased participation in education in the postwar period. Retirement decisions were based on availability of pension or social security funds, accumulation of wealth over the life cycle, and health and family considerations.

There is an important interaction between the tax and welfare systems and participation rates, which makes the budget constraint nonlinear and sometimes nonconvex: Simple models of maximization of utility become complex and difficult to estimate. It is often argued that welfare benefits tend to lower participation rates, especially of women, as their nonlabor income is higher and hence their valuation of nonmarket time is higher. Child care support for families generally increases participation rates for married females.

To summarize, the research on labor force participation has expanded dramatically over the last decade, especially studies of the impact of tax and welfare policy changes. There is little hard evidence to support the popular view that welfare and social security provide disincentives to work. Most of the empirical evidence is based on simple static (one-period) individualistic models that do not allow for family decision-making. Work on household decision-making is still in its early stages, and further research is needed that allows for life-cycle decisions that include household saving jointly with labor-supply decisions and family formation and dissolution. Most empirical studies of labor-force participation find that noneconomic considerations play an important role in explaining behavior.

LABOR LAW

The purpose of labor law is to protect the interests of employers and employees in the workplace. Labor laws grant employers and employees the right to engage in certain conduct such as collective bargaining, strikes, and lockouts, in pursuit of their demands.

In the United States the area of labor law is governed by federal and state statutory law, judicial decisions and regulations, and decisions of administrative agencies. The National Labor Relations Act (NLRA), also known as the Wagner Act, enacted by Congress on July 5, 1935, marks
the foundation of modern U.S. labor law. The NLRA covers all employers and employees involved in businesses that affect interstate commerce. The NLRA protects workers’ rights to strike, associate freely with one another, join labor organizations, and bargain collectively without interference. The NLRA also prohibits employers and unions from engaging in “unfair labor practices” and requires both parties to engage in good-faith negotiations to resolve their disputes.

The NLRA was amended in 1947 by the Taft-Hartley Act (29 U.S.C. § 141 et seq.), which was aimed at reducing the number of industrial disputes and strengthening the power of employers in their dealings with unions. The Taft-Hartley Act was a response to problems that emerged during World War II (1939–1945), such as closed-shop and union-shop agreements, secondary boycotts, and strikes that often resulted in violence. Under a closed-shop agreement, employees are required to join the union as a precondition of employment. Closed shops are the opposite of open shops, which are characterized by the unlawful refusal to hire persons or give them preference in hiring based on their membership in a union. Union-shop agreements do not require employees to be union members as a precondition of employment, but do require employees to join the union or pay union dues within a set period of time after being hired.

The Taft-Hartley Act outlawed the closed shop in the United States, but permits the union shop in states that have not enacted “right-to-work” laws. Right-to-work laws are statutes that discourage collective bargaining and prohibit unions from making union membership a condition of employment. Currently, there are twenty-two states that have right-to-work laws, including Florida, Texas, Virginia, North Carolina, Arizona, Georgia, and Nevada. According to the Bureau of Labor Statistics and the U.S. Census Bureau, the share of jobs in the manufacturing sector rose from 25.4 in 1970 to 34.3 in 2000 in right-to-work states, and all right-to-work states registered a net gain in manufacturing payrolls despite the loss of nearly 875,000 manufacturing jobs nationwide during this period. Moreover, from 1978 to 2000, right-to-work states had lower average annual unemployment rates for all but five years. However, in 2000, per capita disposable income was approximately 10 percent higher in union-shop states than in right-to-work states, and both the poverty rate and income inequality remained higher in right-to-work states than in union-shop states.

The National Labor Relations Board (NLRB) was established under the NLRA to hear disputes between employers and employees. The NLRB’s purpose is (1) to prevent and remedy unfair labor practices, whether committed by labor organizations or employers, and (2) to establish whether or not certain groups of employees desire labor organization representation for collective-bargaining purposes, and if so, which union. The NLRB is composed of five members whose five-year terms are staggered. There is a long-standing tradition that the board consist of a split in political party affiliation, usually a 3 to 2 split in favor of the president’s party. The president designates the chairman of the NLRB. The NLRB’s membership as of 2007 included Robert J. Battista (chairman), Wilma B. Liebman, Peter Carey Schaumber, Dennis P. Walsh, and Peter N. Kirsanow. Usually, both labor and management are represented by attorneys who file grievances in writing with the NLRB, prepare and submit evidence, and argue their positions in the grievances. In cases where the employer-employee relationship is not governed by the NLRA, that relationship may be governed by other federal statutes such as the Federal Service Labor-Management Relations Act (5 U.S.C. § 7101 et seq.) or the Railway Labor Act (29 U.S.C. § 101). State law may also govern the employer-employee relationship where federal statutes do not apply.

Since 2005, new labor legislation has been enacted in several states seeking to improve standards associated with child labor, drug and alcohol testing, equal employment opportunity, human trafficking, the minimum wage, the prevailing wage, time off, wages paid, and worker privacy, among other areas. Currently, seventeen states and the District of Columbia have a higher minimum-wage rate than the federal minimum-wage rate of $5.15 per hour. Kansas and Ohio are the only two states with a minimum-wage rate lower than the federal rate.

The labor movement has been instrumental in the establishment of laws protecting workers’ rights around the globe. For example, over 90 percent of all nations have some kind of minimum wage law. Eighteen out of twenty-seven members of the European Union have national minimum wages, and the People’s Republic of China, too, has established a monthly minimum wage for full-time workers and an hourly minimum wage for part-time workers. Moreover, labor-rights advocates in Europe have had success pushing through legislation that strengthens maternity and paternity rights and protects individuals from discrimination on the basis of age, religion, and sexual orientation, as well as gender, race and disability. The 35-hour maximum work week in France and the Working Time Directive in the United Kingdom, which covers working time, rest breaks, and the right to paid annual leave, are two of the most progressive pieces of labor legislation.

With the growth of democracy and capitalism worldwide, labor law will become more important in balancing the interests of employers and employees in the twenty-first century.

LABOR MARKET

According to textbooks such as Ronald G. Ehrenberg and Robert S. Smith’s Modern Labor Economics (2005), a “labor market” is the place where labor services are bought and sold. The term labor is equated to the term work, not only manual work but also knowledge work. Sometimes, the place where labor services are bought and sold is a clearly identifiable one such as a construction site or a lawyer’s office. Other times, the place is ill-defined, as for the work of most readers of this article, who are hired in one location and who perform labor services in a number of others, such as offices, libraries, home offices, airplane lounges, and hotel rooms.

Labor markets are defined in overlapping ways—by geography (the New York City labor market), occupation (the labor market for economists), or skill level (the labor market for college graduates).

Whatever the defining criterion may be, labor markets always have two sides: labor demand and labor supply. On the labor demand side are firms (including companies, not-for-profit organizations, and government agencies), which hire labor in order to produce goods and services. On the labor supply side are workers, who sell their time in exchange for compensation which, in standard terminology, is called the wage.

On both sides of the labor market, the relevant parties engage in purposeful behavior. In the core model of economics, companies seek to maximize the net present value of profit, which is the difference between the revenues they take in from the goods and services they sell and the costs they incur in producing those goods and services. Individuals, for their part, are assumed to seek to maximize utility, which depends positively on the goods they are able to buy with their income and negatively on the amount of leisure foregone while working.

The amount of labor demanded and supplied are both functions of the wage. The amount of labor demanded in a labor market decreases with the wage, all other things being equal. This negative relationship arises for two reasons: a higher wage induces existing employers to hire fewer workers than they would have if the wage had been lower, and it may induce some of these employers to go out of business entirely and hire nobody. On the other hand, the amount of labor supplied to a labor market increases with the wage, all other things being equal. Here too, there are two basic reasons: a higher wage in one labor market induces some workers to enter that labor market from other labor markets and also induces some individuals who are outside the labor market (the old, the young, full-time students) to seek work in this labor market.

Of course, other things are frequently not equal; labor demand and labor supply are functions of these other things as well. For instance, an improvement in product market conditions will cause more labor to be demanded at any given wage than before, and heightened prestige for a given occupation will cause more labor to be supplied at any given wage than before.

As with other markets, a labor market is said to clear when the amount of labor demanded equals the amount of labor supplied. It is said to be in equilibrium when the economy tends toward a particular set of conditions and, once there, tends to stay there.

Whether an equilibrium is characterized by market clearing or not depends on which equilibrating forces are free to operate in the labor market in question. In the standard labor market models, three fundamental equilibrating forces are postulated. First, firms are free to hire as many or as few workers as they want depending on wages and other conditions of employment. Second, workers are free within limits to move from one labor market to another or into and out of the labor force depending on wages and other conditions of employment. And third, the wage paid is free to rise or fall depending on supply and demand conditions.

When all three of these equilibrating forces are free to operate, the labor market is expected to clear in equilibrium. Wages and employment will therefore reflect supply and demand conditions.

The market-clearing model provides enormous insight. It explains, for example, why workers in the United States are paid so much, why workers in Mexico are paid so little, and why professional athletes are paid so much more than farm laborers.

These examples also highlight two important types of restrictions on equilibration in labor markets. First, every country imposes restrictions on international migration.
Because of the large differences in labor market earnings, a great many workers in Mexico and other countries would like to become American workers, but U.S. immigration law prohibits them from doing so. An estimated 6 million Mexican workers have taken matters into their own hands and have entered the United States illegally. Second, workers differ in terms of their productivity and skills. It is effectively impossible for farm laborers to acquire the skills needed to become professional athletes.

Beyond these barriers to equilibration, which are ubiquitous, there are also settings in which one of the equilibrating forces, the wage rate, is not free to adjust. Wages may be set above the market-clearing level by a variety of institutional forces including minimum wages, trade unions, multinational corporations, public-sector pay policies, and national labor codes. When this happens, the predictable consequence is unemployment. The high rate of unemployment in Europe compared to North America is usually explained in such terms. Infrequently, the wage in a labor market is set not above the market-clearing level but below it. The government of Singapore did this to try to hold down labor costs and maintain international competitiveness. That nation’s wage-restraint policy was halted only when employers persuaded the government to allow them to raise wages so that they could attract more workers and increase production.

Moving beyond this basic labor market model, a number of other features are at the forefront of labor economics modeling today. Efficiency wage models recognize that a higher wage may increase worker productivity, because existing workers have greater incentives to work more efficiently and/or because firms that pay higher wages attract a larger pool of applicants, from whom they can hire more selectively. Human capital models recognize that workers’ skills and productivity can be augmented through education and training. Imperfect information and matching models recognize that it takes time and resources for workers to find appropriate jobs and for firms to find appropriate workers. Models of labor market segmentation and dualism recognize that “good jobs” and “bad jobs” may coexist for workers of a given skill level. Labor market discrimination models recognize that employers, coworkers, and customers may have prejudicial tastes that they exercise in the labor market. In all of these areas, the consequences for employment and wage levels have been carefully worked out.

Finally, a fundamental aspect of labor market economics is that labor markets do not operate in isolation. Wages and employment levels in one geographic area, occupation, or skill group are determined not just by conditions in that labor market but by conditions in other labor markets as well. Multi-sector labor market models, though more complicated than models of individual labor markets, offer insights that models of single labor markets cannot—for example, the understanding that the solution to urban unemployment may be rural development.

**LABOR MARKET SEGMENTATION**

Labor market segmentation theory (LMS) has two principle elements: (1) the labor market can be modeled as consisting of a small number of distinct markets offering different wages, and (2) workers, particularly those from racial and ethnic minorities, women, and new entrants, cannot necessarily find employment in the segment that offers them the highest compensation.

The most common version of LMS is the dual labor market model. This divides the labor market into a primary labor market with well-developed internal labor markets, offering secure long-term employment and higher wages for well-educated, experienced, and senior workers, and a secondary labor market with little job security, short-lived jobs, and wages independent of education and experience. For men, a statistical model of wages with two sectors predicts individual wages much better than does a model with the same number of parameters but only one sector. Moreover, in one sector education and experience have a positive effect on wages, whereas in the other they do not. For women, the dual labor market model does not fit the data well.

Mainstream labor economists have also sometimes modeled the labor market as consisting of two sectors: government and private, manufacturing and nonmanufacturing, skilled and unskilled, and so on. But LMS differs from mainstream models of the labor market in two important ways. First, it implies that low wages are associated with undesirable job characteristics, whereas conventional models imply that workers in jobs with otherwise undesirable characteristics receive a compensating (higher) wage differential. Second, in LMS, wages do not adjust to clear the market. There are workers who are qualified for desirable jobs but are unable to find employment in those jobs.

Labor Supply

In fact, high wages are often associated with good job characteristics. There is relatively little evidence that workers are compensated for bad job characteristics. This is not decisive evidence in favor of LMS. Advocates of the standard view argue that we have relatively poor data on workers’ earnings potential. Workers with high earnings potential take their compensation partly in the form of high wages and partly in the form of better working conditions, which explains the positive relation between wages and working conditions.

LMS is sometimes interpreted incorrectly as meaning that there is little mobility among sectors. Low mobility might mean most workers are happy where they work. In contrast, workers initially trapped in the secondary sector would change sectors upon obtaining primary-sector employment. The existence of queues for good jobs is the most significant departure of LMS from the conventional view, but it is difficult to test. Although compared with secondary-sector jobs, primary-sector jobs pay more and have characteristics that most people prefer; some secondary workers may not be excluded from primary jobs, but instead prefer secondary jobs and willingly accept the lower pay. However, the overrepresentation of some groups in the secondary sector is only consistent with free choice if their members are more likely than others to like secondary jobs. For some groups, such as African Americans, this is implausible and suggests that some workers in the secondary sector would prefer primary-sector employment.

LABOR SUPPLY

For economists, “labor supply” usually means the hours of work, usually per week, offered for pay or profit. This definition therefore excludes unpaid household work and voluntary work. Usually, the question of labor-force participation (the question of whether a person is working or looking for work) is treated separately. Research on both the theoretical and applied labor supply exploded in the 1980s and 1990s, with the work ranging from models of individual behavior in a static one-period model to dynamic multi-period models for a household. Simple theoretical models that gave a backward-bending supply curve (where labor supply first increased and then decreased with wage rates, for which little evidence exists) have given way to empirical labor-supply curves that are usually (but not always) positively sloped with respect to the wage rate. Beginning in the late twentieth century, much of the focus of research has been on labor supply as a whole, not on particular firms, industries, or occupations.

The concept of “labor supply” is defined for economies with a well-developed labor market; that is, a market where wage labor is employed. The concept of labor supply in less developed countries (LDCs) is less clearly defined, because culture, history, and institutions affect labor supply. In some LDCs, women are not involved in the formal labor market, and the labor activities that women perform may be limited by tradition, either for religious or cultural reasons. Because precapitalist conditions exist in LDCs, labor in these nations is often tied to a particular feudal lord, and the worker does not have the freedom to move from one employer to another, or from one location to another.

In LDCs, as the economy develops, labor moves from the agricultural sector to the industrial sector. W. Arthur Lewis, in his seminal 1954 paper “Economic Development with Unlimited Supplies of Labour,” put forward a dual-economy model in which the surplus agricultural labor (defined as labor with a zero marginal product) moved to the industrial (modern) sector, providing a nearly infinite supply of labor at a constant wage. This provided a boost to economic development because the industrial sector could expand with a “surplus” (i.e., a profit) being created with cheap labor. The rapid growth of the Chinese economy in the first decade of the twenty-first century provides an example of how surplus labor from agriculture can provide a boost to economic growth.

In general, there are important differences in labor supply for males and females. Biology, history, and society have led to women spending more time in housework, child rearing, and various other domestic duties. For various reasons, including discrimination, society appears to have accepted a gender segregation of roles in the labor market. For example, women work in the textile industry while men work in mining, and women work as primary school teachers while men work as lawyers. Fortunately, many of these stereotypes are breaking down slowly, at least in most Western countries.

The labor supply in a particular economy can increase through population growth (natural increase), immigration, an increase in people employed or looking for work, and through workers offering longer hours of
work in each period. Although the labor supply of different educational or skill levels is considered in many models, the issue of the efficiency of labor services (i.e., how hard and diligently a person works) is usually ignored.

In most models of labor supply, the determination of the hours of work is derived from an assumption of utility-maximizing individuals who face given wage rates and prices and a time constraint. In all these models, it is assumed that there is a disutility from work—that is, it is assumed that people do not like working. There is a good deal of evidence, however, from psychologists, sociologists, and industrial relations experts that work provides an individual with a set of contacts, imposes a time structure on the waking day, provides social status and identity, and enforces activity (see Jahoda 1982). Further, an unemployed person often suffers from a level of despair that may lead to mental illness.

Standard neoclassical models are set up to analyze competitive capitalist economies with a well-developed wage-labor market. The utility function, which is unchanging over the life cycle, depends on leisure and consumption goods. An increase in the wage rate leads to a substitution effect (leisure becomes expensive) and an income effect (a person can purchase more leisure and goods). If leisure is a normal good, then these two effects work in opposite directions. The net effect of a wage rate change is therefore ambiguous. The introduction of income taxes and social security payments make the analysis more complex, since the budget constraint becomes nonlinear.

In a novel extension to the concept of labor supply, George Becker argued in a 1965 paper that individuals choose “commodities” that are produced by combining consumer goods with the individual’s time. Hence, a consumer good that is purchased, such as meat, also needs time (e.g., cooking time, washing-up time) to form the “commodity” called dinner. The time used in cooking thus has an “opportunity cost.” Alternatively, the “dinner” can be purchased in a restaurant with less time spent in obtaining it. The choice of cooking at home or eating out depends on the opportunity costs of time. For a professional person, the opportunity costs of cooking a meal are generally too high. This approach is especially useful in analyzing nonmarket work done (mainly) by women.

In an early model, labor supply was dependent on current wages and (expected) future wages, such that people would offer to work less in the current period if future wages were expected to be higher. Robert Lucas and Leonard Rapping deal with the intertemporal substitution of labor in “Real Wages, Employment, and Inflation” (1969). In advanced models, labor supply is dependent on the planned time path of consumption goods and leisure, along with a choice of saving and wealth accumulation over an entire lifetime. A critical assumption in these dynamic models is of a utility function that is not affected by habits or learning (intertemporal separability over time), as this could make the wage rates depend on individual’s behavior (see Card 1994). There are significant differences in the labor supply of males and females due to cultural and institutional factors. Typically, the female labor supply is significantly affected by the number of preschool children in the family.

Expanded models of labor supply allow for joint household decision making, with bargaining between husband and wife (see Vermeulen 2002). The aggregate supply of hours depends on the number of people who are willing to work (given wage offers and their reservation wage) and the hours offered per person. Individuals are assumed to work out a “reservation wage,” meaning a wage below which they are not willing to work because the opportunity cost of leisure is too high. This reservation wage is obviously influenced by an individual’s age, education, experience, family commitments, social security benefits, and wealth status. Changes in the minimum wage are likely to lead to a change in the distribution of reservation wages, because the idea of “fair wages” will also change (see Falk, Fehr, and Zehnder 2005). Changes in reservation wages can also affect the aggregate supply of labor.

It is generally assumed that the individual can work as many hours at a given wage as she or he desires (either within a firm, choosing different offers from different firms, or with multiple jobs). It is also usually assumed that there are no institutional constraints (e.g., a specified work week for a full-time person), and that the nonavailability of work (i.e., involuntary unemployment) is not a factor. Most estimates of labor supply are based on people who are working. This creates a selection bias, because it excludes those who want to work but cannot find work or have refused the wage offered to them. However, an individual can influence his or her wage through an appropriate investment in human capital, such as acquiring new skills or additional education. In some labor markets (especially for highly skilled labor) an individual may be able to bargain for a package of wages, hours, and other perquisites.

Some empirical regularities have been seen in OECD (Organisation for Economic Co-operation and Development) countries in the post-war period. These include an increase in the number of women working, a decrease in the number of older males working, a fall in the average number of hours worked, and educated people working longer hours. Most of the research on this subject has focused on an econometric estimation of labor supply for males, females, and households. Econometric estimation has moved progressively from time-series data to cross-
section data to panel data. Most estimates of labor supply find a small positive link between wages and hours worked—known as “elasticity,” the percentage increase in labor supply as a result of a one percent change in the wage rate—although there is a large element of “unexplained” variance. A major interest has been the extent to which welfare benefits and changes in tax rates affect the labor supply. Policy changes in these and other areas could affect people’s decision whether or not to seek work. Again, because most labor-supply models are based on data on working people, the possibility of selection bias must be considered.

Labor supply is also important from a policy perspective. How people respond to changes in tax rates, social security payments, and other institutional features like minimum wages are all relevant. Much of the evidence is based on simple models of single-person (or “unitary”) households, and is thus subject to debate. The evidence on many of these issues is very controversial, especially the impact of minimum wage on employment. And as Richard Blundell and Thomas Macurdy point out, there is little evidence to support the view that welfare programs have a disincentive effect on the labor supply.

Even though there have been significant advances in the theoretical modeling of labor supply, and in econometric estimation techniques, there are still large gaps in our understanding of the impact of policy changes on labor supply. Models need to be extended to households in which people decide simultaneously whether to work and how many hours to work over a longer period, including their saving behavior, and with some allowance made for the existence of demand-constrained choices. The existence of persistent unemployment in most OECD economies suggests that a basic underlying assumption of labor supply models is unrealistic, namely that workers can choose whether to work and how many hours to work.

**LABOR THEORY OF VALUE**

Fundamentally, the labor theory of value is a prohibition: it asserts that produced means of production cannot be sources of surplus value, and hence of profit. Once seen as an essential component of Marxian economics, it is now a divisive issue even amongst economists who describe
themselves as Marxist. It is rejected by many non-neoclassical economists, and of course by the neoclassical school in general. However, it is still championed by several sub-schools of Marxian economics, and will no doubt always be part of the ideological appeal of anti-capitalist political parties.

The concept that work, or relative effort, was the just determinant of the ratio in which two commodities were freely exchanged was first aired by Aristotle (c. 450–388 BCE) in his *Nicomachean Ethics*. Starting from the premise that “the good has rightly been declared to be that at which all things aim” (Bk. 1, chap. 1), Aristotle deduced that, for justice to prevail, commodities should exchange in relation to the amount of work embodied in them: “Let A be a builder, B a shoemaker, C a house, D a shoe. The builder, then, must get from the shoemaker the latter’s work” (Bk. 5, chap. 5). However, Aristotle subsequently added demand, or utility, as the basis of exchange, thus conflating the two great traditions in the determination of value and exchange: that relative prices are set either by the objective effort expended in production, or by the subjective utility enjoyed in consumption.

By the time of Adam Smith (1723–1790) and David Ricardo (1772–1823), these two perspectives were regarded as essentially contradictory. The then-dominant classical school subscribed to the former, while the then-nascent neoclassical tendency asserted the latter. However, though Smith identified work as the basis of exchange, and labor as its measure, he also argued that nonhuman inputs could be productive, and hence sources of profit: “labouring cattle, therefore, ... not only occasion ... the reproduction of a value equal to their own consumption, ... but of a much greater value” (Smith [1776] 1904, Bk. 2, chap. 5). He also argued that only “in that early and rude state of society which precedes both the accumulation of stock and the appropriation of land” (Bk. 1, chap. 6) could commodities actually exchange in proportion to the labor embodied in them.

Ricardo also treated labor as a measure of value, rather than its sole source. The assertion that labor was not only the measure but also the source of value, and hence profit, was first made by Karl Marx (1818–1883).

Marx argued that profit could originate even when commodities exchanged at their costs of production. He assumed that commodities exchanged at their value, where value was “socially necessary labor-time,” so that capitalists purchased labor at its value, which was a subsistence wage (the value of labor-power, signified by \(v\)). These commodities might take, say, six hours of direct and indirect labor to produce (where indirect labor included the depreciation of machinery and consumption of raw materials).

Marx then drew a crucial distinction between labor (actual work activity) and labor-power (working ability). Workers receive a wage that is equal to the value of their labor power; however, the value created by workers will normally be greater than this. Surplus value (signified by \(s\)) arises from the fact that the working day is longer (typically twelve hours in Marx’s day) than the time required for laborers to create value equal to the value of labor-power (say, six hours). Surplus value arises from the unpaid labor time that accrues to capitalists as a legal right, and not because of capitalists’ contribution to production. The capitalist gains this unpaid labor time “for free” from the labor contract. Expansions in the length of the workday, increases in the speed of work, or productive changes in the organization of work will all extend this gap between the value of labor-power (\(s\)) and the value of labor activity (\(v + \delta\)), giving rise to a surplus (\(\delta\)).

So, in Marx’s analysis, surplus value does not arise because commodities exchange above their value: the commodity that is produced is exchanged according to its value, and laborers are paid a wage that is equal to the value of labor-power. Exploitation, which for Marx means the creation of surplus value, occurs because workers create value that is greater than the value of their labor-power. Marx argued that labor-power is the only commodity with the capacity for value greater than its own value, and he regarded the distinction between labor and labor-power as his important contribution to political economy.

Marx assumed that \(s/v\), the “rate of surplus value,” was constant across industries, though it could of course vary over time. He was emphatic that all other inputs to production (signified by \(c\) and measured by their depreciation) made no net contribution to surplus: “However useful a given kind of raw material, or a machine ... may be, though it may cost £150 ... it cannot, under any circumstances, add to the value of the product more than £150” (Marx [1867] 1887, chap. 8). Surplus, and therefore profit, thus emanated solely from labor.

The rate of profit, which Marx defined as \(s/(c + v)\), was positively related to the rate of surplus value and negatively related to the ratio of \(c\) to \(v\) \((s/v), the ratio of capital to labor, which Marx termed the organic composition of capital). Allied with an alleged tendency for the organic composition of capital to rise over time, this led to Marx’s prediction of a falling rate of profit that would ultimately lead to the demise of capitalism via a socialist revolution.

Critics of Marx’s economics have long argued that the dilemma for the labor theory of value was that it could not be made consistent with the competitive equalization of the rate of profit across different industries, when the organic composition of capital differed from one industry to another. Marx’s solution of what became known as the
transformation problem was strongly challenged by Ladislaus von Bortkiewicz (1868–1931) and remains a contentious issue within Marxian economics.

By the end of the twentieth century, economists inspired by Marx had broken into two broad camps: those who accept the labor theory of value and those who do not (most of whom would describe themselves as belonging to other schools of non-neoclassical thought). Indeed, one of the most influential present-day economists inspired by Marx, Ian Steedman, believes that “the project of providing a materialist account of capitalist societies is dependent on Marx’s value magnitude analysis only in the negative sense that continued adherence to the latter is a major fetter on the development of the former” (Steedman 1977, p. 207).

Anwar Shaikh (1984) presents an orthodox defense of Marx’s value theory. Two other important attempts to sustain the labor theory of value are the temporal single system interpretation that the determination of price from value is a dynamic process in which the labor theory of value can be sustained (Foley 2000), and the empirical argument that, while subject to theoretical criticism, the proposition that prices are proportional to labor values is empirically valid (Cockshott and Cottrell 1998, 2005). Both the theoretical and empirical defenses are subject to criticism from other non-neoclassical economists (Mongiovi 2002; Podkaminer 2005).

Most critiques of the labor theory of value, as with Steedman’s pivotal contribution, effectively discourage consideration of other aspects of Marx’s thought, such as his philosophy of dialectical materialism. An exception here is Steve Keen’s argument that Marx’s philosophy itself contradicts the labor theory of value. Keen argues that, after 1857, the concept of a dialectic between the objective use-value of a commodity and its exchange-value became Marx’s fundamental axiomatic base, rather than the labor theory of value itself.

Marx mocked Ricardo for not having an explanation of the gap between the value of labor and labor-power: “Value of labour is not identical with wages of labour. Because they are different. Therefore they are not identical. This is a strange logic. There is basically no reason for this other than that it is not so in practice.” In contrast, Marx argued that “what the capitalist acquires through exchange is labour capacity: this is the exchange value which he pays for. Living labour is the use value which this exchange value has for him, and out of this use value springs the surplus value and the suspension of exchange as such” (Marx [1857] 1973, pp. 561–562).

The distinction between use-value and exchange-value was also central to Marx’s explanation of surplus value in Capital: “The past labor that is embodied in the labor-power, and the living labor that it can call into action … are two totally different things. The former determines the exchange-value of the labor power, the latter is its use-value” (Marx [1867] 1887, chap. 7, sec. 2). Keen (1993) asserts that Marx misapplied this dialectic to machinery to sustain the labor theory of value, and that when properly applied, Marx’s dialectic concludes that the means of production are also sources of surplus value. This critique thus maintains Marx’s philosophy, while also rejecting the labor theory of value.

LABOR UNION

A labor union is typically an association of wage and salary earners aimed at improving the welfare of its associates through raising the bargained wage above the competitive level, improving working conditions, and preserving occupational levels. These aims can be achieved by unions using a number of strategies, according to the institutional framework under which unions and employers operate, general economic conditions, and political economy considerations.

In most industrialized economies, wages are largely determined through collective agreements between unions and employer confederations. Total output is shared between the two parts according to the relative bargaining power. These agreements are usually binding for a proportion of total employees that does not include union members only. The proportion of contracts usually covered by collective agreements is known in the literature as union coverage. The membership rate among wage and salary earners is referred to as union density.

The bargaining process may take place at the firm, industry, regional, or national level and may involve other issues, such as the work schedule, working conditions, holidays, and training. The attitude of unions during the bargaining process may vary, according to how much they internalize the consequences of the bargaining decisions on the economy as a whole. This amount to unions being more or less coordinated with employer confederations in defining bargaining outcomes that can be beneficial or detrimental for economy-wide growth and welfare. Alternatively unions may adopt bargaining strategies aimed at improving the welfare of their associates only, regardless of the consequences on the economic system. For example, unions mainly representing insiders—that is, employed workers—may bargain for a higher wage, therefore improving the welfare of associated employees, despite the adverse effect on outsiders, including the unemployed and new entrants in the labor market.

Sometimes unions’ actions and organization may be defined and managed under specific regulations. For example, in the United States public sector workers do not have the right to strike, while in other countries certain limitations apply in order to guarantee a minimum amount of public services during collective actions. Other regulations apply to the collection and management of union dues. For example, all employees may be required to pay union dues within a fixed period of time after hiring, although unions may be limited in their ways of spending financial resources collected from nonmembers.

One possible representation of union preferences is based on the assumption that union members are identical. The union objective function consists then of the expected utility of the representative member. This amounts to the utility associated, respectively, to the state of employment and unemployment, that is, by the real wage \( W \) and the reservation wage \( W^* \), weighted by the probability of being in each of the two states. With \( N \) and \( L \) being, respectively, the labor force and the employment level, and \( v() \) an indirect utility function, this can be written as \( E(U) = \frac{L}{N} v(W) + \left(1 - \frac{L}{N}\right) v(W^*) \) with \( v'(W) > 0; v''(W) \leq 0 \).

Union members are, however, typically heterogeneous. In this case, the union objective function will depend on the mechanisms regulating the functioning of the union. If unions are perfectly democratic organizations, then their objectives will typically depend on the preferences of the median member. However, because they are collective organizations, unions respond to political economy incentive structures, like firms and political parties, and their leaders may be assigned discretionary power. In this case, union leaders may operate for objectives that are different from their organization’s statutory objectives.

Wage-bargaining models can be classified into two main theoretical frameworks, known in the literature as right to manage and efficient bargaining. Under the right-to-manage approach, unions and firms bargain over the wage, with firms setting labor demand given the bargained wage. As a result, the bargaining outcome will always be on the labor-demand curve. This approach can be rationalized under a simple Nash framework, with the bargained wage \( W \) being the result of the following maximization problem: \( \max B = V(W)\Pi(W)^{1-\gamma} \), where \( V(W) \) and \( \Pi(W) \) are, respectively, the bargaining outcome gains for unions and firms, and \( \gamma \) (with \( 0 < \gamma < 1 \)) is the bargaining power of unions. A higher wage will increase the employed workers’ utility, but at the same time it will lower the firms’ profits per worker as well as the aggregate employment level.

Under the efficient bargaining approach, it is shown that unions and firms can reach bargaining outcomes that are Pareto-improving with respect to the right-to-manage hypothesis. The bargaining equilibrium is then located on the contract curve, that is, on the locus of the tangency points between firms’ isoprofit curves and unions’ indifference curves. The exact location of the equilibrium on the contract curve will depend on the relative bargaining power \( \gamma \). The empirical evidence is mainly consistent with the first setting.

Historically, in many industrialized countries, union density rates have increased especially during the expansion of the industrial sector. Recent decades, characterized by a declining industrial sector and the development of a service-oriented economy in many advanced economies,
have witnessed heterogeneous patterns in union density rates, with a decline in some countries and an increase in others. These patterns seem to have followed the general institutional settings prevailing in each country as well as the ability of unions to adapt their objectives and strategies to new economic environments. As a result union density rates across Organization for Economic Cooperation and Development (OECD) countries display a significant amount of variation, from a minimum of around 10 percent in France, the United States, and Spain in 2001 to a maximum of around 80 percent in Finland and Sweden. The same is true for union coverage that ranges from a minimum of 14 percent in the United States to above 90 percent in Austria, Belgium, Finland, France, and Sweden. Even within the same country, unions are characterized by different membership rates across sectors. For example, in the United States private sector unions represent around 8.5 percent of workers, whereas public sector unions represent around 30 percent of workers in their sector.

LABOUR PARTY (BRITAIN)

The Labour Party currently led by Tony Blair (b. 1953) has formed the governments of Britain since 1997 through its successes at three consecutive general elections in 1997, 2001, and 2005. It is now a party committed to the “New Labour” ideas of its leader, who maintains a “third-way approach” that accepts that both the state and public enterprise should jointly contribute to Britain’s economic recovery. Peter Mandelson and Roger Liddle in their book The Blair Revolution (1996) state that “New Labour believes that it is possible to combine a free-market economy with social justice: liberty of the individual with wider opportunities for all; One Nation security with efficiency and competitiveness” (p. 1).

As part of this strategy Blair forced the party to drop its traditional Clause 4 when he became leader in 1994, replacing it with an amorphous alternative and thus abandoning a commitment to public ownership, playing down the importance of traditional trade-union and working-class demands, and opening up the possibility of the party capturing more white-collar and middle-class support, the middle ground in British politics. He was able to do so largely because of the way in which both Neil Kinnock (b. 1942), leader between 1983 and 1992, and John Smith, leader from 1992 to 1994, had transformed the party after Labour’s disastrous general election of 1983. Gerald Kaufmann, a Labour MP, had described Labour’s manifesto of 1983 “as the longest suicide note in history,” tied as it was to nationalization in the hands of an increasingly left-wing party that was becoming unpopular in the country and that was ultimately out of power from 1979 until 1997.

In the early 1980s the Labour Party was organized into local constituency Labour parties, which were usually dominated by the bloc-vote influence of the trade unions and often could be operated by a small minority of activist members. The trade unions and left-wing activists usually dominated the local parties, and therefore their representatives often held sway in the annual national conference of the party, which often elected a predominantly left-wing National Executive Committee. Fearful that a small extreme minority could easily dominate the party, Kinnock pressed for a number of reforms, including instigating four policy reviews between 1988 and 1991, one of which, Meet the Challenge and Make the Change (1989), challenged Labour’s shibboleth of nationalization. His policy reviews also ended Labour’s commitment to full employment and universal provision within Britain’s welfare state. Kinnock set up committees to be responsible for Labour’s manifesto commitments and policies, the centralizing authority around the Labour leader. Trade union power at the annual party conference was also reduced to 40 percent of the vote, considerably less than the 1987 bloc vote, and the rest of the vote was based upon an individual ballot of rank-and-file members. The method of electing the party leader was changed, and by the late 1980s the voting in leadership and deputy-leadership elections was established on the basis of One Member One Vote (OMOV). Effectively, then, Kinnock centralized power around the Labour Party leader, neutralized left-wing policies, and reduced the power of the trade unions within their local constituencies and at party conference. It was out of these changes that Blair was able to press forward with his more moderate to right-wing agenda of “New Labour.”

The present Labour Party is thus a far cry from the organization formed as the Labour Representation Committee in 1900, which became the Labour Party in 1906. This had been an alliance of trade unions and socialist groups committed to operating as an indepen-
dent working-class organization within a parliamentary system. Led at various times by James Keir Hardie (1856–1915), Ramsay MacDonald (1866–1937), and Arthur Henderson (1863–1935), it had emerged quickly, was drawn into the wartime coalition of World War I (then referred to as the “Great War,”) and was able to form its first, albeit minority, Labour government in 1924. By that time the party had become officially socialist as a result of accepting Clause 4 (clause 3d) in its 1918 constitution, which committed it to the public ownership of the means of production. MacDonald’s first government was short-lived, but its essential moderation helped to allay the fears of newspapers that announced the first Labour government’s formation in January 1924 with the headlines “Lenin dead, MacDonald in power.” This government was defeated in the 1924 general election, which was dominated by the Zinoviev, or “Red Letter,” scare, in which what was almost certainly a forged letter was published as evidence that the Soviet Union wished to use the Labour Party to extend the influence of communism in Britain.

MacDonald formed another, minority, Labour government in 1929, but it too was defeated after a brief existence as a result of the mounting economic crisis of 1931, when the Labour cabinet was divided on cutting unemployment benefits by 10 percent. The government resigned but MacDonald continued as prime minister of a national government, and Labour was decimated, cut down from 289 to 52 seats, in the general election of October 1931.

Labour remained in the political wilderness until May 1940, when Clement Attlee (1883–1967), elected leader in 1935, became a member of Winston Churchill’s wartime cabinet. Out of office, the party rethought its policies, and partly because of this, and partly because of the leftward shift during World War II, it won the general election of July 1945 with 393 seats and a thumping majority of 146 seats in the House of Commons. As a result, Attlee led his first administration from 1945 to 1950, and narrowly won a second term from 1950 to 1951. These two Attlee governments were immensely talented, with members such as Ernest Bevin (1881–1951), a foreign secretary who pushed for the North Atlantic Treaty Organization in 1949, and Aneurin (Nye) Bevan (1897–1960), who inspired the introduction of the National Health Service in 1948.

Nevertheless, in the early 1950s the Labour government was divided, and it collapsed after Bevan left in 1951 over his opposition to the threatened prescription charges on medicines. The Labour Party was defeated at the 1951 general election and remained out of office for thirteen years, during which it was divided between its left-wing public-ownership groups and its right wing, led by Labour Leader Hugh Gaitskell, who wanted to drop public ownership from his policies. Gaitskell died in 1963, but Labour returned to power under the then moderate, but once left-wing, Harold Wilson (1916–1995) in 1964, and won again in the 1966 general election. However, the Wilson administrations faced serious economic problems, had to devalue the pound, and fell out with the trade unions over how to deal with strikes. Defeated in the 1970 general election, the party brokered a deal with the trade unions in the early 1970s that saw it win two general elections in 1974. Nevertheless, the Wilson and James Callaghan governments of 1976 to 1979 were unable to introduce policies of redistributing income in return for the small wage increases that trade unions were going to accept under the so-called “social contract,” and as a result the Labour Party lost the general election of 1979 following the strike-prone “winter of discontent.”

The Labour Party came under the influence of left-wing trade unionists in the early 1980s when led by Michael Foot (b. 1913). However, the disastrous general election of 1983 augured the change of leadership and a move to the right that occurred under Neil Kinnock, John Smith (1938–1994), and Tony Blair. It is now epitomized by the “New Labour” party of Tony Blair.

**LADEJINSKY, WOLF**

1899–1975

Wolf Isaac Ladejinsky significantly influenced global debates and policy surrounding rural development and cold war strategy. He was perhaps the most influential advocate of using agrarian reforms to win the support of the peasantry in order to preempt communist appeals— “stealing communist thunder,” in one of his memorable formulations. The most significant effect of his policies...
Lafargue, Paul

was, perhaps, the decade of social conservatism resulting from post–World War II land reforms in Taiwan and, especially, Japan.

Ladejinsky fled Soviet power in the Ukraine in 1922, after expropriation of his father’s business. His life was subsequently dedicated to the defeat of communism. In his view—much influenced by Bolshevik successes—communist mobilization fed on unattended peasant grievances; the remedy was preemptive policy against rural injustice.

Four years after landing in New York City, Ladejinsky entered Columbia University; he graduated in 1928. Though he made extensive studies of Soviet state farms as a graduate student, he did not finish his PhD Ladejinsky began working for the U.S. Department of Agriculture in 1935; by the end of the World War II, he was head of the Department’s Far East division. In 1945 he joined General Douglas McArthur’s staff overseeing American occupation forces in Japan, where he forcefully advocated land reform to promote social peace and centrist politics during reconstruction. Ladejinsky’s “root-and-branch” land reform in Japan under occupation authority broke the power of large landlords and established the landless as small farmers. Farmers became the backbone of conservative governance that served many American foreign-policy objectives. Contemporary consensus is that land reforms contributed significantly to postwar Japan’s political stability and economic growth. Ladejinsky’s model of “stealing communist thunder” by redistributing land was also successful in Taiwan, in ways parallel to developments in Japan, but proved impossible to implement in China, where Mao Zedong’s revolution promoted agrarian reform.

Time magazine observed in 1955 that the “Americanization of Wolf Ladejinsky was a copybook success story. An immigrant, he won an education and renown as a U.S. agricultural expert who helped to stymie the Communists in the Far East.” Ironically, this successful anticommunist was accused of having communist sympathies by Eisenhower’s secretary of agriculture; Ladejinsky lost his job in 1955 as one of many victims of anticommunist hysteria organized by Senator Joseph McCarthy.

After having had both success and failure in Asia, and losing his government job, Ladejinsky served as adviser to the U.S.-backed Diem regime in South Vietnam from 1956 to 1961. Vietnam proved more like China than Japan; Ladejinsky’s attempt to use land reform as the antidote to communism founded on the inability of Diem’s regime to confront landlords. Ladejinsky subsequently served as adviser to the Ford Foundation and World Bank, concerned with Indonesia, Nepal, and the Philippines. He ended his career in India, keenly observing rural dynamics and promoting agrarian reform until his death in 1975.

LAFARGUE, PAUL 1842–1911

Paul Lafargue was a Haitian-Cuban-French Marxist economist, activist, politician, and writer, who considered himself black and referred to himself as African in letters to the German socialist Friedrich Engels. One might say with much justification that Lafargue was Cuba’s first socialist.

FAMILY BACKGROUND AND EDUCATION
Lafargue was born on January 15, 1842, in Santiago, Cuba, the most popular and culturally Africanized part of the country to this day. His father, Francisco/François Lafargue (b. c. 1791–1803, d. 1870), was a wine seller, landowner (with New Orleans, Cuban, and Bordeaux properties), and tobacco or coffee planter. His mother was Ana Virginia Armaignac/Armagnac (1803 or 1810–1899). His paternal grandparents were Jean Lafargue (d. c. 1791–1803), a French colonist in St. Domingue from the Bordeaux area, and Catalina Piron (d. after 1891), a “mulatto” woman from St. Domingue. His maternal grandparents were Abraham Armagnac, the scion of a French Jewish colonialist family in St. Domingue, and Margarita Fripie/Frijie, a Carib woman residing in Kingston, Jamaica. François’s mother, Carlina, fled from St. Domingue to Santiago, Cuba, probably in 1803, after the death of her French husband, Jean Lafargue, François’s father, during the Haitian Revolution (1791–1803). She evidently was pregnant with François at the time of the flight, for he was born in Santiago.
In 1891, when Paul was running for the Chamber of Deputies from Bordeaux, his grandmother Catalina provided proof of her husband's French nationality. This implies that by this time Catalina also had marriage documents, or some other written token of her son's legal relationship to Jean Lafargue. Francisco was registered with the French consul in Santiago as a Frenchman, as evidently was his mother, Catalina. Actually, however, Francisco was a French citizen by virtue of article 59 of the 1685 Code Noir, which provided that any slave freed from French captivity became a French citizen. This implies that Catalina or her ancestors were freed slaves, and suggests that her descendants had documents in 1891 to prove her French slave and freedman origins.

In any case, Catalina Lafargue was among the approximately twenty thousand civilian refugees who fled from the island of Hispaniola to Cuba during the Haitian Revolution. In 1809 the Spanish government of Cuba forced Catalina and her son Francisco to flee once more. She went to New Orleans because Louisiana was the nearest location with a large French population and culture. They remained in the French Quarter and neighboring areas from about 1809 until 1814. In New Orleans the Lafargues were well-established Creoles as well. Catalina apparently never remarried, and little more is known about her.

Paul Lafargue's parents married in 1834, evidently in Santiago, Cuba. During the next seventeen years, they had one child, Paul (or Pablo, his name at baptism), and acquired property in Cuba, New Orleans, and perhaps in other places as well. The Lafargue's Cuban property included slaves, which they held at least until 1866. Paul attended the Colegio de Santiago, a Jesuit primary and middle school. Between 1814 and 1851, his parents acquired the property that made Francisco a landowner, wine seller, and slave-managed coffee plantation owner.

In 1851, three years after the Revolution of 1848 had eliminated slavery in France and its colonies, Paul's parents leased their Cuban property, La Maison de Saint Julian, with its slaves, and moved to Bordeaux, France. Paul was nine years old at the time. His parents retained possession as well of a house in Santiago. Apparently, relatives of theirs who remained in Cuba managed the leased property and the house. Paul's parents left at this time to avoid the increasingly burdensome laws directed against free blacks and mulattoes.

In Bordeaux, which at that time had a population of around 180,000, Paul studied for eight years under a private teacher, a Messieur Roger-Mice, and then in the lycées of Bordeaux and Toulouse. In the lycées, he received a good education in classical languages, literature, philosophy, and science.

Under Napoléon, a boarding school system existed in which boys spent ten months a year at gender-segregated school for eight or nine years, seeing little of their families. They wore military uniforms. Lycées for boys in Bordeaux at that time included the Lycée Michel Montaigne and Lycée Bertrand de Born. Lafargue evidently lived at home while attending one of these lycées. Lycées for boys in Toulouse included the Academie Royale de Toulouse (established 1345). Lafargue graduated from the Toulouse lycée in 1861 with a baccalaureate degree.

After completing lycée, Lafargue moved to Paris to study pharmacy, hoping to become an apothecary. He changed his mind, however, and enrolled at the Faculté de Medecin in Paris, studying medicine there from 1861 to 1865. His professors included his mentor, Jules-Antoine Moilin, and Carriere, his advisor. Moilin, a psychologist, also wrote on social economics, and was a left-wing radical who was ultimately executed by the government. Carriere, whose first name is not known, was himself driven into exile and began teaching physics and chemistry in London at St. Bartholomew's Hospital Medical School (now part of the University of London). Having been expelled from the University of Paris in 1863 for insulting church and state, Lafargue elected to continue his medical studies in London, gaining entrance to St. Bartholomew's in 1865 with Carriere's help. Lafargue graduated in July 1868 as a physician, qualified for the Royal College of Surgeons as an assistant surgeon, and practiced at the hospital.

MARRIAGE AND CHILDREN
Lafargue had joined the social democratic labor movement in France. Because of his residence in England for medical school, he was accredited as a representative of the Prudhonist French labor party and the French section of the First International in London in 1865. At that time, he was converted to Marxism by debates with Karl Marx at the meetings and at Marx's home. He met Marx's daughter Laura (1845–1911), and they were married in 1868. They had three sons, all of whom died in infancy or early childhood—Charles Étienne (1868–1872), François (1870–1870), and Marc-Laurent (1871–1872).

For their honeymoon, Paul and Laura were supposed to come to the United States, where his parents owned property in New Orleans, but Paul's commitments to the international socialist movement preempted this trip. Quite possibly, the Lafargues, or the Armagnacs, had and still have relatives and descendants in New Orleans and/or the United States, because this was fifty-four years after they had left New Orleans, and seventeen years after they had left the Caribbean for Europe. If they owned property in New Orleans, presumably someone had been in charge of managing their property during that period, and that someone was likely to have been a relative. The Lafargue...
family was well established in both Bordeaux and Louisiana in the nineteenth century.

REVOLUTIONARY ACTIVIST AND POLITICIAN
After completing his medical residency in London in 1870, Lafargue moved back to Bordeaux with his wife. That year, he participated in the Paris Commune. As a result, he was arrested, and his papers were burned by police in Paris and Bordeaux. Lafargue founded the Marxist labor party in France, as well as the French, Spanish, and Portuguese sections of the First International. From 1872 to 1882, he and Laura lived in London, and then returned again to France. From 1891 to 1893 Lafargue represented a district in Lille in the Chamber of Deputies. In 1898 he also completed a thesis in law.

WRITING CAREER
Lafargue was a prolific writer, but his lasting legacy is to have introduced Marx’s magnum opus, Das Kapital, to France and Italy. In 1890 Lafargue began work on a French translation of excerpts from Kapital that encompassed only the first nine chapters. The selected excerpts presented Marx’s theory of historical materialism and class struggle, his distinction between use value and exchange value, his labor theory of value, and the beginning of his scheme of simple reproduction. Published in 1893, this translation featured an introduction by Vilfredo Pareto, which was intended as a refutation. This version of Kapital was also published in Italian in 1894 with a translation by Pasquale Martignetti, an Italian socialist and the translator into Italian of two of Engel’s works.

The inclusion of Pareto’s introduction in this version of Kapital was particularly significant. Pareto approved the theory of historical materialism and class struggle, but opposed the labor theory of value. He did not address the theory of simple reproduction. At this time, he was a supporter of socialism, and in this book, he began the research that led in 1897 to the construction of his renowned general equilibrium model of socialist economic planning. This collaboration between a Marxist theorist and a quasi-socialist economist (Pareto) is unique at this high level of rigor, and has had immense consequences for the theory of macroeconomic modeling for more than a century, despite the later waning of Pareto’s sympathy for socialism. All national economic planning owes its origin to Kapital.

Although Marxist theoreticians had been writing and talking about trusts for decades, none had published a book on the subject until Lafargue published Les trusts américains in 1903. Using Moody’s Manual, he identified 793 trusts, capitalized at $69.781 million, out of a total U.S. “fortune” of $485 million. Five railroad groups held additional capital. He focused his analysis on the petroleum, tobacco, and steel trusts, in which most of this capital was concentrated, and discussed their leading firms: Standard Oil, American Tobacco, United States Steel, and the Morgan, Gould-Rockefeller, Harriman-Kuhn-Loeb, Vanderbilt, and Pennsylvania railroad groups. Lafargue offered a straightforward empirical analysis, with no novel argumentation or conclusions.

The Right to Be Lazy was first published in French as a series of articles in L’Egalite in 1880, then appeared as a pamphlet the following year, and was first translated into English in 1898. It was a sardonic attack on the Protestant ethic that Lafargue argued underlay capitalism. Rather than a right to work, workers had a right not to work, or to work as little as possible. Lafargue took this idea from Aristotle’s dictum that merchants and other workers had no time to develop the mind, and so were inferior to pure intellectuals or philosopher kings. Practically, implementing this idea would have the effect under capitalism of reducing unemployment by sharing the available paid work. Lafargue, however, argued not only for abolishing work, but that people engage in hedonism with their newly found free time. This pamphlet became the most translated socialist work after the Communist Manifesto, and was translated into Russian before the latter had been.

The modern Zerowork tradition may be said to have begun with Harry Cleaver (b. 1944) of the University of Texas and the two issues of the New York journal Zerowork published in 1975 and 1977. The journal engaged in polemics leading back to the materialist class struggle theory of classical Marxism of the 1848–1917 period, and against the idealist tendency promoting Marx’s philosophical ideas of the early 1840s. These polemics even represented the Russian Communist leader Leon Trotsky (1879–1940) as an idealist. A liberal strand of this movement, led by Jeremy Rifkin, argues that it is now technologically possible to abolish work. Another strand followed the economic anthropologist Marshall Sahlins (b. 1930) and others in showing that primitive hunter-gatherers worked less than the proletariat in capitalist societies, because they are not forced by capitalists to produce economic surplus value to be extracted; thus, they limit their desires, producing only what is necessary for subsistence. This tradition may be viewed as a Lafarguean movement, in inspiration, one attempting to show that work is neither desirable nor necessary, or even possible.

LAGGING, LEADING, AND COINCIDENT INDICATORS

The index of leading indicators comprises economic indicators that generally turn down and up prior to the business cycle peaks and troughs designated by the Business Cycle Dating Committee of the National Bureau of Economic Research. The index of coincident indicators consists of data series whose turning points tend to coincide with peaks and troughs in overall economic activity, and the index of lagging indicators comprises indicators whose turning points generally occur after recessions and recoveries begin.

The three indexes are published by the Conference Board, a not-for-profit business-membership organization. Prior to 1996, they were published by the Bureau of Economic Analysis (BEA) of the U.S. Department of Commerce.

The ten components of the leading index are:

1. The length of the workweek for production workers in manufacturing.
2. Initial weekly claims for unemployment insurance.
4. A measure of slower deliveries by vendors.
5. Manufacturers’ new orders for nondefense capital goods.
6. Permits issued for the construction of new housing units.
7. Stock prices.
8. The inflation-adjusted money supply.
10. The difference between the interest rate on ten-year Treasury securities and the federal funds rate, which banks charge one another on short-term loans.

Various explanations have been offered for why these indicators turn up and down before the economy does. Stock prices, for example, are regarded as a reflection of people’s confidence in the economy, and such confidence (or the lack thereof) is self-fulfilling. If people think the economy will do well, they will behave in ways (e.g., spending more freely) that will cause the economy to do well. Also, changes in stock prices create changes in wealth that—with a lag—lead to changes in consumer spending.

While the leading index is intended to predict cyclical turning points in the economy, it has major weaknesses as a forecasting tool. One weakness is that the time period between the turn in the index and the turning point for the economy varies greatly, before both recessions and recoveries. In 1993, when the BEA revised the index, it reported that the lead time provided by its new index had varied in the post–World War II (1939–1945) period from five months before the July 1953 peak to twenty months before the August 1957 peak, and that the lead time provided by the index that was being replaced had varied even more—from two months before the recessions that began in 1981 and 1990 to twenty months before the August 1957 peak. Under a widely accepted rule of thumb that a decline in the index is not meaningful until it has lasted at least three months, the leading indicators failed to signal the recessions that began in 1981 and 1990. Also, the index sometimes gives a false signal of a recession, as in 1984, when a large drop in the index was not followed by a downturn in the economy.
Lagrange Multipliers

The BEA has pointed out, too, that the size of a drop in the leading index is not a sign of the severity of an ensuing recession; a mild recession may be preceded by a sharp drop in the index, and a severe recession may be preceded by a moderate decline in the index.

The coincident index includes:

1. The number of employees on nonagricultural payrolls.
2. Inflation-adjusted personal income less transfer payments (such as unemployment insurance benefits).
3. Industrial production (a measure of the output of the manufacturing, mining, and utility industries).
4. Inflation-adjusted manufacturing and trade sales.

The index is regarded as a gauge of the current health of the economy, although in the “jobless” recovery from the recession that ended in November 2001, payroll employment did not hit its low until August 2003.

The index of lagging indicators comprises:

1. The average duration of unemployment (inverted).
2. The ratio of inventories to sales in manufacturing and trade.
3. The change in labor cost per unit of output in manufacturing.
4. The average prime rate of interest charged by banks.
5. Commercial and industrial loans outstanding (adjusted for inflation).
6. The ratio of consumer credit outstanding to personal income.
7. The change in the consumer price index for services.

These series measure the types of forces (debt burdens, for example, and price and credit pressures) that build up during expansions and that can bring an expansion to a close if they build up excessively. Thus, the ratio of the coincident index (which measures economic activity) to the lagging index serves as a leading indicator of recessions. A decline in the ratio during an expansion, suggesting that expansion-threatening forces are building up faster than economic activity is increasing, is a leading indicator of a possible recession.

The Conference Board publishes cyclical indexes for a number of countries other than the United States, and the makeup of those indexes differs somewhat from that of the U.S. indexes. For example, the coincident index for Mexico includes retail sales and the (inverted) unemployment rate, and the leading index for Australia includes the sales to inventories ratio.

LAGRANGE MULTIPLIERS

Lagrange Multipliers is a mathematical device introduced to find local extrema of a function subject to constraints. Problems of this general type are ubiquitous in the social sciences. For instance, they arise as optimization problems for quantities that depend on variables that satisfy some additional relations. An example in neoclassical economics is the optimization problem of the utility function with restrictions imposed by a fixed budget.

A typical problem of this type involves a function $f(x_1, \ldots, x_n)$, say, dependent on $n$ variables. One seeks values for the variables $x_i$ so that $f$ has a local extremum; that is, $f$ has a local maximum or minimum. This requirement is equivalent to the statement that all partial derivatives of $f$ vanish:

$$\frac{\partial f}{\partial x_i} = 0 \text{ for all } i = 1, \ldots, n.$$  

Quite often the variables $x_i$ are not independent of each other but must satisfy some additional conditions. In such cases one cannot simply solve the above condition on the partial derivatives of $f$ since the variables $x_i$ are not independent of each other. The Lagrange multiplier technique can be employed in cases where the constraints on the variables can be expressed as equations:

$$g_\alpha(x_1, \ldots, x_n) = 0, \text{ for } \alpha = 1, \ldots, k.$$  

In such cases the above extremization problem can be expressed in a different form. Consider a new function $F$ defined through the relation:

$$F(x_1, \ldots, x_n, \lambda_1, \ldots, \lambda_k) = f(x_1, \ldots, x_n) + \sum \lambda_\alpha g_\alpha(x_1, \ldots, x_n).$$
This definition introduces \( k \) new variables \( \lambda_\alpha \)—one for each constraint \( g_\alpha \). The sum in the above expression is over \( \alpha \). The new variables \( \lambda_\alpha \) are called Lagrange multipliers.

In terms of \( F \) it is possible to express the previous problem of constrained extremization as a simple extremization problem. Since \( F \) depends on \( n + k \) variables, finding local extrema for \( F \) can be split up into two sets of equations:

\[
\frac{\partial F}{\partial x_i} = \frac{\partial f}{\partial x_i} + \frac{\partial g}{\partial x_i} = 0 \quad \text{for all} \; i = 1, \ldots, n,
\]

as well as:

\[
\frac{\partial F}{\partial \lambda_\alpha} = g_\alpha = 0 \quad \text{for all} \; \alpha = 1, \ldots, k.
\]

The second set of equations imposes the constraints \( (g_\alpha = 0) \), while the first set imposes a new condition. This apparently new condition actually reduces to the condition that the partial derivatives of \( F \) vanish once the constraints \( g_\alpha = 0 \) are taken into account.

As an example from neoclassical economics, consider the problem of optimizing utility for a consumer who can buy two commodities, \( a \) and \( b \), with price per unit \( p_a \) and \( p_b \) respectively. The consumer is constrained to spend within his or her budget \( w \). Let the number of commodities of each kind, \( a \) and \( b \), purchased by the consumer be given by \( x_a \) and \( x_b \), respectively. The budget of the consumer imposes the constraint:

\[
p_a x_a + p_b x_b \leq w.
\]

This states simply that the total price paid for the two commodities should be less than the available budget. In many neoclassical models the inequality is transformed into an equality. This is justified by hypothesizing one of a number of characteristics of consumer behavior. One hypothesis that justifies this modification is that the consumer is “insatiable” that is, the consumer will buy to the maximum of his or her buying ability. In any case, these hypotheses lead to the modified constraint:

\[
p_a x_a + p_b x_b = w.
\]

The utility function \( u \) is a measure of the happiness of the consumer. The utility is a function of \( x_a \) and \( x_b \): \( u = u(x_a, x_b) \). Consumers in neoclassical economics base their behavior on maximizing their utility function while satisfying the budgetary constraint. This problem is of the general type discussed above with \( f = u(x_a, x_b) \), and \( g(x_a, x_b) = p_a x_a + p_b x_b - w \). To illustrate the method, consider a utility function given by \( u(x_a, x_b) = x_a x_b \).

To apply the Lagrange multiplier method one constructs a new function:

\[
F(x_a, x_b, \lambda) = u(x_a, x_b) + \lambda g(x_a, x_b) = x_a x_b + \lambda(p_a x_a + p_b x_b - w).
\]

Setting the partial derivatives of \( F \) to zero, one finds:

\[
0 = \frac{\partial F}{\partial x_a} = x_b + \lambda p_a
\]

\[
0 = \frac{\partial F}{\partial x_b} = x_a + \lambda p_b
\]

These equations can be solved to yield:

\[
x_a = w/2p_a
\]

\[
x_b = w/2p_b
\]

These give the proportions of each of the commodities that optimize the utility function. The Lagrange multiplier

\[
\lambda = -w/2p_a p_b
\]

has an economic interpretation. The Lagrange multiplier can be expressed as a derivative of \( F \):

\[
\lambda = \frac{\partial F}{\partial w}.
\]

It tells one how \( F \) changes when \( w \) is varied. Since on the extremum of \( F \), the constraint is satisfied \( F \) coincides with \( u \), the utility. The Lagrange multiplier is thus a measure of how the utility \( u \) changes when the budget \( w \) is varied, with this interpretation the Lagrange multiplier \( \lambda \) is called the shadow price.

**LAGS, DISTRIBUTED**

Often when we try to model statistical relationships, we tend to use contemporaneous values. For example, if we want to model changes in consumption because of a change in disposable income, we may try to run the regression \( \Delta Y = \alpha + \beta \Delta X + \varepsilon \), where \( \Delta Y \) is the percentage change in consumption and \( \Delta X \) is the percentage change in the disposable income, \( \alpha \) and \( \beta \) are the regression parameters, and \( \varepsilon \) is the random error. The relationship works very well, but it has been documented that people demonstrate “consumption inertia”—that is, the
consumption habits of consumers do not change right away in response to an increase in the disposable income. Because consumption expectations are formed by past changes in income, this class of models is called backward-looking expectations models. The best way to capture consumption inertia is to include in the regression model not only the current change in disposable income but also previous changes. If an independent variable ($\Delta x$) appears more than once, with different time lags, then the model is called a distributed lag model. Generally, with only one dependent variable and one explanatory variable, the distributed lag model is represented as 

$$y_t = \beta_0 + \beta_1 x_{t-1} + \beta_2 x_{t-2} + \ldots + \beta_n x_{t-n} + \epsilon_t.$$  

where $\beta_i$ are coefficients, $x_{t-i}$ are the lagged values of the explanatory variable and $\epsilon_t$ is the independent white noise random error.

To demonstrate the distributed lag model empirically, with personal consumption data let $y_t$ be the change in U.S. personal consumption expenditure in quarter $t$, and $x_t$ be a change in U.S. personal disposable income in quarter $t$. The results of a regression of one lag of personal disposable income are:

$$y_t = .005 + .124 x_t + .142 x_{t-1} (3.52) (1.89) (2.17) \quad (t\text{-stats}).$$

This illustrates that a 1 percent change in disposable income induces 0.124 percent of the change in the current consumption. However, last quarter’s change in disposable income has statistically significant (t-statistics in the parenthesis) influence on the change in the consumption. A 1 percent increase in disposable income would cause about 0.142 percent increase in current consumption. The implication of this finding is that changes in personal disposable income have lasting influence on the changes in consumption.

The obvious statistical question then is why estimate the model with only one lag. How many lags are appropriate? This has long been one of the problems with the distributed lag models, even in the early work of Irving Fisher (1937) in the 1930s. Researchers such as Jan Tinbergen (1949) suggest including lags until the coefficients of the lagged variables become insignificant or the signs of the coefficient become erratic. There are several problems with this kind of ad hoc specification. First, there is no guidance in terms of lag length. Second, if the sample size is small, then as the lag length increases statistical inference may be somewhat shaky, with fewer degrees of freedom. Finally, successive lags tend to have high correlations (multicollinearity), leading to smaller t-ratios and incorrect inferences.

One way to reduce the number of lags and the extent of multicollinearity is to use L. M. Koyck’s (1954) adaptive expectations model. In this type of model, in addition to the explanatory variable a lagged dependent variable is included and is represented as $y_t = \alpha + \beta_1 x_t + \beta_2 y_{t-1} + u_t$, where $u_t$ is the error term. The adaptive expectation model can be illustrated by using the data on personal consumption expenditures and disposable income. The results of the model are:

$$y_t = .007 + .067 x_t + .107 y_{t-1}$$

The coefficients of the above model have some interesting interpretations. The coefficient of disposable income ($x_t$) shows short-run impact of a change in disposable income on consumption. A 1 percent change in disposable income would cause a 0.67 percent increase in consumption in the short run. The estimate 1.15 percent $(0.107/(1 – 0.067))$ provides the long-run impact of a change in disposable income on consumption. The results reveal that a 1 percent increase in disposable income would cause consumption to go up by 1.15 percent in the long run.

If the dependent variable is random, the lagged dependent variable may also be random, and including a random explanatory variable in the model may produce biased and inconsistent estimates. Thus, in order to use this model it is essential to verify that the lagged dependent variable is not correlated with the random errors. In addition, in the above models serial correlation in the errors cannot be tested using normal autocorrelation statistics. One of the assumptions of infinite distributed lag models such as Koyck’s is that the coefficient on the lag variables declines geometrically as the lag length increases. If the coefficients do not behave in this manner, then the above lag structure may not be suitable. In these circumstances, you need a more flexible model that would incorporate a variety of lag structures, such as Shirley Almon’s (1965) distributed lag models.

To estimate a flexible model such as Almon, we must a priori specify the lag length to verify the changes in the size of the coefficients. If $\beta$s decrease at first and then increase with higher lags, $\beta$s can then be approximated by a second-degree polynomial because we have one size change. The more the turning points, the higher the degree of polynomials. We can illustrate the Almon distributed lag model by using the data on personal consumption and disposable income. First, we assume that change in consumption depends on the current change and preceding two-quarter change in disposable income. Second, we also assume that $\beta$s can be approximated by a second-degree polynomial. The results of this estimation of are $y_t = 0.006 + 0.121 z_0 - 0.047 z_1 - 0.064 z_2$, where $z_s$ are constructed as a linear combination of $x$ (change in disposable income) series. For this example of two lags and second-degree polynomial, the $z_s$ are:
From the above estimates, original \( \beta \)s can be obtained and are presented as \( y_t = 0.006 + 0.103 x_t + 0.121 x_{t-1} + 0.001 x_{t-2} \).

The above values are provided in standard econometric software programs. Although this model offers more flexibility than Koyck's model, there are still problems with this technique. First, there is no real guidance as to the selection of lag length or the degree of polynomial. Second, the constructed \( z \)s are likely to exhibit multicollinearity, which may lead to statistically insignificant coefficients due to large standard errors. Nevertheless, the distributed lag models in general are very useful in modeling issues when the dependent variable exhibits delayed reaction to changes in the independent variable.

**LAISSEZ-FAIRE**

The doctrine of laissez-faire was first systematically developed by the physiocrats in France. It was at first primarily considered a moral doctrine that sanctified the freedom of the individual and had implications for economic life, not just an economic policy doctrine. Later laissez-faire came to be understood mainly as an economic policy doctrine.

Folklore has it that during the reign of Louis XIV (1638–1715), the finance minister, Jean-Baptiste Colbert (1619–1683), asked a group of French businessmen what the government could do to aid the cause of commerce, and the response was *laissez-faire*, or let the people do as they freely choose. The social-philosophic doctrine that emerged opposed government interference in economic affairs beyond providing the minimum functions of ensuring peace, administering justice, and providing basic public goods. In the English-speaking world, the laissez-faire doctrine came to be identified with Adam Smith (1723–1790) and in particular the argument for free trade associated with *An Inquiry into the Nature and Causes of the Wealth of Nations* (1776).

The moral theory aspects of the doctrine of laissez-faire remained in classical political economy, but the economic policy implications came to dominate the debates around the doctrine. The idea of economic freedom and limited government would be developed in the century after Adam Smith by Jeremy Bentham (1748–1832), J. B. Say (1767–1832), Frédéric Bastiat (1801–1850), and John Stuart Mill (1806–1873). Even as Mill made an explicit case for exceptions to the laissez-faire principle in economic life, he argued that “laisser-faire, in short, should be the general practice: every departure from it, unless required by some great good, is a certain evil” (Mill [1848] 1976, p. 950).

From the beginning, however, critics of laissez-faire attempted to paint a picture of extremism and lack of concern for the least advantaged in society. This characterization of the position was immortalized by Charles Dickens’s (1812–1870) portrayal of Scrooge (a thinly veiled depiction of Herbert Spencer [1820–1903]) and the claim that rather than give aid to the poor we should allow the surplus population to decline naturally. But as Jacob Viner (1892–1970) pointed out in his “The Intellectual History of Laissez Faire,” only “unscrupulous or ignorant opponents of it and never its exponents” used the term *laissez-faire* to mean a position of “philosophical anarchism, or opposition to any governmental power or activity whatsoever” ([1960] 1991, p. 200). Instead, the term *laissez-faire* as used by its systematic exponents meant freedom of choice and trade and a limitation on the scope of governmental activities to defense against foreign powers, establishment of a system of justice to prevent members of the society from oppressing others in that society, and the maintenance of essential public works and institutions. Laissez-faire, Frank Knight (1885–1972) declared, “simply means freedom, in the particular case of economic policy: freedom of economic conduct from dictation by government” ([1967] 1999, p. 435).

The nonsubtle reading of laissez-faire argues that the position is claiming that the individual pursuit of self-interest is enough to realize a benevolent social order irrespective of the social rules of interaction that are in place. In fact, the critics read the doctrine as insisting that there is an absence of governance, rather than just limits on the scope of government. In this regard, advocates of the doc-
trine of laissez-faire are accused of being unreasonable and doctrinaire. F. A. Hayek (1899–1992), in fact, argues that nothing has done more harm to the cause of economic liberalism than a “wooden insistence” on the principle of laissez-faire (1945, p. 17). A more nuanced and appropriate reading of laissez-faire would emphasize the essential role of institutions of governance (though not necessarily provided only by government) in explaining how a benevolent social order can result from individuals freely choosing.

Critical to understanding the defense of the doctrine of laissez-faire are two subsidiary arguments. First, the defender of laissez-faire must present a demonstration through the logic of economic analysis of the “invisible hand” proposition (see, e.g., Nozick 1974, pp. 18–22). Second, the defender of laissez-faire will proceed to conduct a comparative analysis (both theoretical and empirical) of market versus governmental decision-making within the sphere of economic affairs (see, e.g., Buchanan and Tullock 1962). The combination of these two subsidiary arguments, often alongside a moral stance derived from natural law theory, can be found in almost any presentation of the laissez-faire position from Smith to Hayek, from Bastiat to Milton Friedman (1912–2006).

As Viner pointed out in his essay “Adam Smith and Laissez Faire,” even when Smith “was prepared to admit the system of natural liberty would not serve the public welfare with optimum effectiveness, he did not feel driven necessarily to the conclusion that government intervention was preferable to laissez faire. The evils of unrestrained selfishness might be better than the evils of incompetent and corrupt government” (Viner [1927] 1991, p. 104). In order to justify intervention, Smith argued, one would have to demonstrate not only that individuals freely choosing would not advance the public welfare, but also that government officials would be in a position to know better what was in a man’s interest than he would be himself. This was a position that Smith vehemently refused to concede in the realm of economic affairs. As Smith put it:

The statesman, who should attempt to direct private people in what manner they ought to employ their capitals, would not only load himself with a most unnecessary attention, but assume an authority which could safely be trusted, not only to no single person, but to no council or senate whatever, and which would no-where be so dangerous as in the hands of a man who had folly and presumption enough to fancy himself fit to exercise it. (Smith [1776] 1976, bk. IV, chap. 2, p. 478)

On the other hand, the individual from the vantage point of his local situation is in a better position to judge what is the best course of action for himself. Smith, it is important to stress, did not presume that acting self-interestedly was enough to ensure a benevolent social order. Self-interest is what guides the statesman to overburden himself; it is also what leads to Oxford dons not satisfying the educational demands of their students (Smith [1776] 1976, bk. V, chap. 1, p. 284) and to teachers of religious doctrine being less zealous and hardworking in the state-supported religious sects as compared to those sects that rely solely on voluntary contributions (bk. V, chap. 1, p. 309). Self-interest also leads the businessman to conspire with his competitors to set prices (bk. I, chap. 10, p. 144) and to seek out protection from foreign competitors (e.g., bk. IV, chap. 2, pp. 489–490). It is self-interest that is behind the sophistry of the merchants and the manufacturers in the quest for monopolistic status, just as it is self-interest among professors and preachers when they seek secure incomes and protection from competitors in the instruction of philosophy and religious doctrine.

Self-interest is also what drives the refinements in the division of labor, the coordinative activities of an economy guided by relative price movements, and the innovations of the entrepreneur. Self-interest is not unique to laissez-faire, but a regime of laissez-faire (within the specified institutions of natural liberty) will channel self-interest in a direction that will maximize the likelihood of a social order of peace and prosperity. When the institutions of natural liberty are absent, or government attempts to thwart their development, Smith’s claim was that tyranny and poverty would result. As he put it in the notebooks that preceded the Wealth of Nations:

Little else is requisite to carry a state to the highest degree of opulence from the lowest barbarism, but peace, easy taxes, and a tolerable administration of justice; all the rest being brought about by the natural course of things. All governments which thwart this natural course, which force things into another channel or which endeavor to arrest the progress of society at a particular point, are unnatural, and to support themselves are obliged to be oppressive and tyrannical. (Smith [1776] 1976, p. xI)

The laissez-faire doctrine would latter become identified with the harmony of interest doctrine, a doctrine that claimed that the competing interests of individuals could be reconciled through the market mechanism. The proposition is actually older than Smith, and can be traced back to Voltaire (1694–1778). In the sixth of his Letters Concerning the English Nation, Voltaire discusses how even passionate warring factions can be reconciled through commerce:

Take a view of the Royal Exchange in London, a place more venerable than many courts of justice,
where the representatives of all nations meet for the benefit of mankind. There the Jew, the Mahometan, and the Christian transact together, as though they all professed the same religion, and give the name of infidel to none but bankrupts. There the Presbyterian confides in the Anabaptist, and the Churchman depends on the Quaker’s word. At the breaking up of this pacific and free assembly, some withdraw to the synagogue, and others to take a glass. This man goes and is baptized in a great tub, in the name of the Father, Son, and Holy Ghost: that man has his son’s fore-skin cut off, whilst a set of Hebrew words (quite unintelligible to him) are mumbled over his child. Others retire to their churches, and there wait for the inspiration of heaven with their hats on, and all are satisfied. (Voltaire [1733] 1994, pp. 29–30)

This doux-commerce thesis, which argued that commerce was a civilizing influence on humanity, has been identified with Montesquieu (1689–1755) and Voltaire, and then received its systematization in the works of David Hume (1711–1776) and Smith. It is very much a part of the underlying argument for the laissez-faire doctrine. Understanding the logic of this argument and its implications came to be synonymous with becoming an economist or a classical political economist.

Critics of the laissez-faire doctrine emerged from the beginning and tended to focus on variants of the following arguments through the years:

1. Poverty traps that cannot be escaped through free choice.
2. General glut that results from overproduction or underconsumption.
3. Monopoly power that emerges naturally in the market and allows businesses to exploit consumers.
4. Exploitation of the working class that pushes wages down to subsistence and compels laborers to work in harsh and unsafe conditions.
5. External economies that generate situations where desirable goods are underproduced on the market, and undesirable goods are overproduced on the market.
6. Public goods that are not supplied by the market due to free-rider problems.

Beginning in the late nineteenth and continuing throughout the twentieth century, a stream of economic schools of thought rose to challenge the presumption for laissez-faire. In fact, the American Economic Association was formed by economists who were decidedly non-laissez-faire thinkers, but instead were government reformers and activists. Laissez-faire was identified in their minds with an economic policy of noninterventionism, which meant that the social ills of monopoly, unemployment, inequality, and exploitation would go unchecked. The institutional school of Thorstein Veblen (1857–1929), John Commons (1862–1945), and Clarence E. Ayres (1891–1972) was critical of the laissez-faire doctrine. John Maynard Keynes (1883–1946) declared “The End of Laissez Faire” in the 1920s, and the development of Keynesian economics in the 1930s and 1940s transformed the discipline of economics from one that sought philosophic understanding to one that provided tools for social control. Mid-century arguments for market socialism and market failure theory added to the dismissal of the presumption for laissez-faire that was in the classics from Smith to Mill. And the arguments against laissez-faire from Karl Marx (1818–1883) to Paul Samuelson relied on some version of the six critiques listed above. Even the most sophisticated modern criticisms of laissez-faire (e.g., asymmetric information, network externalities, or behavioral irrationalities) rely on a variant of these basic criticisms that have been leveled since the beginning of the history of the idea.

The argumentative strategy of the opponents of laissez-faire usually took the form of: (1) characterization of the laissez-faire position as based on unrealistic assumptions concerning man (e.g., atomistic and hyperrationality); (2) depiction of reality that highlighted deviations from what would be theoretically optimal (e.g., deviations from marginal cost pricing); and (3) a willful ignoring of the costs of decision-making when government is called upon to serve as a corrective to social ills.

During the twentieth century, three figures emerged as the heirs to Adam Smith and the defenders of the laissez-faire doctrine—F. A. Hayek (1974 Nobel Prize in Economics), Milton Friedman (1976 Nobel Prize in Economics), and James Buchanan (1986 Nobel Prize in Economics). Keep in mind what was argued in the beginning of this entry concerning Smith’s argument—that there were two intellectual moves in the laissez-faire argument: first, the invisible hand; second, the comparative analysis on nonmarket decision-making. Hayek, Friedman, and Buchanan argued that more often than not the breakdown of the invisible hand was a consequence of governmental policy that had previously not been considered by the critics of laissez-faire. Adam Smith, they reminded everyone, did not argue that self-interest under any conceivable set of circumstances would produce a beneficial social order. Self-interest within a system of clearly defined and strictly enforced property rights could be relied upon to channel self-interest to serve the public welfare, but if property rights are unclear or weakly enforced, self-interest may very well produce undesirable outcomes. The tragedy of the commons, in other words, is not a challenge to Smith (or Hayek, Friedman, and
Buchanan) but a confirmation of their basic insight into how the “invisible hand” works. Second, even if the market order failed to produce the best of all possible outcomes (as it inevitably always did at any point in time), the critic must not leave the costs of governmental decision-making unexamined (including unintended and undesirable consequences). The standard twentieth-century argument for interventionism presumed both that the government possessed the knowledge to solve the problem, and that the decision process was relatively costless because the government actors were acting as economic eunuchs. Works such as Hayek’s The Road to Serfdom (1945) and The Constitution of Liberty (1960), Friedman’s Capitalism and Freedom (1962) and Free to Choose (1980, with Rose Freidman), and Buchanan’s The Limits of Liberty (1975) and Democracy in Deficit (1977, with Richard Wagner) challenged the government as a corrective presumption, and helped forge a revitalized case for laissez-faire in the late twentieth century.

In the narrative on laissez-faire just constructed, little reference was made to the actual historical record for the simple reason that such a discussion would require multiple entries. The critics of laissez-faire attribute the late nineteenth-century robber barons, the miserable working conditions of the poor in early twentieth century, the Great Depression, and the bigotry of racial segregation to laissez-faire capitalism. The defenders of laissez-faire, on the other hand, reject each of these interpretations and attempt to show either that the root cause of the problem was government interference with the competitive process or that the competitive forces of the economy were in fact alleviating the problem at the time that government stepped in to claim credit for easing social tension. One side sees market forces as ameliorating social ills and reconciling conflicts, while the other side sees the market as augmenting social ills and aggravating conflicts. This has been an ongoing argument for three centuries, and it does not appear to be resolvable in a clear-cut empirical manner. Instead, the debate turns on analytical arguments, empirical evidence and counterevidence, and explicit or implicit moral judgments.

LAKATOS, IMRE 1922–1974

The pivotal philosophical debate of twentieth-century Anglo-American philosophy originated with Thomas Kuhn’s 1962 The Structure of Scientific Revolutions. Kuhn (1922–1996), along with Imre Lakatos and Paul Feyerabend (1924–1994), made the history and sociology of science central to conceptions of scientific progress and rationality. Lakatos, a Hungarian émigré who escaped the failed 1956 revolution, became Karl Popper’s (1902–1994) best and favored student, but he joined forces with Kuhn and Feyerabend against Popper’s refusal to see scientific method as having historical roots and hence being subject to change. Lakatos maintained Popper’s anti-posi-
tivist view that scientific knowledge has no epistemological foundation, but that progress occurred through continual criticism and revision. Lakatos made the historicism in that view explicit by critically elaborating Popper's approach into an interpretative method for the history of science and mathematics. Instead of Popper's ahistorical "logic of scientific discovery" Lakatos saw an historically changing logic of criticism and the growth of scientific knowledge. But like Popper and Feyerabend, and unlike Kuhn, Lakatos recommended a normative conception of scientific method, analogous to normative philosophical models of political or civic processes. Lakatos created his critical theory of science using a sui generis historiographical approach for reconstructing the scientific present as a value-laden history of progress and decline.

The historiographical toolkit is Lakatos's methodology of scientific research programs. In contrast to Popper's confrontations of falsifiable theories, with their risky predictions and hence potential refutations, Lakatos argued that individual theories are poorly chosen "units" for scientific change. In practice, as Kuhn and Feyerabend dramatically demonstrated, the best theories can be formally inconsistent; they may contradict stable observations or received theories, or they may violate traditional canons of scientific method—not all at once, but individually or opportunistically, as needed for theory improvement. Lakatos also assumed no theory-neutral observational basis to conclusively refute a single theory. Hence there was no guarantee that confirmatory or refuting data might not itself be reinterpreted and overturned, thus making conclusive refutation of single theories either impossible or subject to unrealistic and overcomplex methodological criteria.

This messy and chaotic milieu of chronic uncertainty requires the intelligence and flexibility of working scientists, whose theories Lakatos organized in terms of long-term research programs. These need not coincide with projects of individual researchers. Instead, they are a post festum historical reconstruction used to characterize scientifically recognized progress or failure. Lakatos proposes a philosophical model to characterize just what, in long-term patterns of theory choice, empirical discovery, and interpretation, led to a recognition, perhaps erroneous, by scientific communities as achievement or decline. A research program, then, was defined as a series of theories that were loosely united by a shared hard core of key principles, ranging from inchoate metaphysical ideas to favored modeling approaches; a positive heuristic of plans for generating theoretical improvements, and turning theories into operational models for addressing open problems, hopefully creating novel confirmations or predictions; ancillary touchstone and observational theories, used to interpret and organize a changing basis of theory-laden "facts" relevant to the program; a protective belt of theories or models insulating the program from critical attack; perhaps ad hoc theories or models needed as temporary fixes; an inventory of Kuhnian puzzles, contradictions, and anomalies awaiting resolution; and an environment of competing research programs against which relative progress is gauged.

Thus "scientific" describes not individual theories, but sequences of theories in time, not necessarily coordinated by any single individual or group. Such science, then, is either progressive or degenerating, the outcome measured by the presence or absence of novel confirmations, persistent puzzles and contradictions, powerful model development, and more or less ad hoc fixes—all of these judged relative to competing programs with a shared domain of problems, relevant phenomena, and research objectives. Lakatos's historiography of research programs is a theory of modern scientific progress in which a role for scientific truth is reduced in proportion to the Faustian ambitions of theoreticians and experimenters.

Lakatos and others rewrote episodes from the histories of various sciences, using research program categories: the phlogiston and oxygen programs of Joseph Priestley (1733–1804) and Antoine-Laurent Lavoisier (1743–1794); the wave and corpuscular programs for light; nineteenth-century atomic-versus-phenomenological theories of heat; modern plate tectonics; classical political economy from Adam Smith (1723–1790) to David Ricardo (1772–1823) and Karl Marx (1818–1883); and several segments of twentieth-century physics. These projects led to successes and failures, the latter occurring when a major change, like the replacement of classical physics with relativity theory, or the emergence of modern science altogether, is forced into Lakatos's research program categories, which can be thought of as a nuanced conception of Kuhn's "normal science," and absent Kuhn's confusing normative views. Lakatos saw this historical work as "scientific," meaning that methodological reflection itself was an ongoing, theory-laden activity of understanding the "phenomena" of the scientific past. As in science proper, no perfect match is expected between historical theory and historical data, implying, as Lakatos points out, no "true" scientific consciousness: our knowledge of science is imperfect and uncertain, just as in science proper. Lakatos's dialectical histories demonstrated that understanding past knowledge is possible only through some contemporary normative criteria for what counts as scientific, whether clearly articulated or not. His project was to make that condition of historical knowledge his primary lesson for the new philosophy of science. Lakatos and others carried out this project by using the methodology of scientific research programs as a historiographical guide and toolkit. Feyerabend identified the characteristic feature of modern scientific knowledge as a constantly
expanding horizon of facts. Lakatos thought it best to comprehend that post-Renaissance process using normative and philosophical concepts that make historical knowledge an object of rational, even scientific, self-understanding.

LAND CLAIMS

A *land claim* is the pursuit of recognized territorial ownership by a group or individual. In modern nation-states, the vast majority of such claims have been advanced by indigenous peoples who have been dispossessed of land and resources in the course of imperial expansion and nation building. In the context of a worldwide rise in aboriginal political power since the 1970s, aboriginal leaders have initiated land claims in an effort to reverse the marginalization of Native societies in countries dominated by non-Native peoples and to provide a means of wealth and security. While indigenous peoples have pursued land claims across much of the globe since at least the early 1980s (see Fondahl et al. for Russian examples), they have become particularly well developed in the countries that have emerged out of the former British settler colonies: Canada, the United States, Australia, and New Zealand. As with so many other struggles for the acknowledgement of minority rights, land claims are often marked by protest and conflict between, on one side, sets of property owners, corporations, and governments that stand to benefit from the maintenance of the status quo and, on the other side, aboriginal peoples who hope to regain control of territory and resources. In the context of social science research and study, understanding land claims requires consideration of the intersection of geography, politics, economics, and social pluralism.

At the root of the pursuit of modern land claims is the assertion of *title* by aboriginal peoples. Claimants argue that they hold ownership of land and resources based upon long-term occupation and use of particular territories. Thus, for a land claim to proceed, title must be ascertained and recognized by a country’s legal institutions. In different jurisdictions, recognition of Native title has varied greatly. In Canada, for example, aboriginal claims of ownership are backed by the Royal Proclamation of 1763, in which the British Crown affirmed Native ownership of land and resources in Britain’s North American colonies where obvious occupation and use was in evidence. Under this law, British settlers were obliged to negotiate in good faith with Native peoples for the transfer of land and resources (Usher 2003, p. 377). Since the early 1990s, land and resource claims advanced by a number of Native groups in British Columbia have been based on the historical fact that the requirements of the Proclamation have not been met in the province (Rossiter and Wood 2005, pp. 358–359). The United States, another outgrowth of British colonization, also recognized the existence of aboriginal title through the negotiation of historic treaties between the federal government and individual Native groups (Hendrix 2005, p. 765). Modern land claims in the United States, such as those advanced in the 1980s and 1990s by the Western Shoshone Nation in Nevada (see Luebben and Nelson 2002) have resulted from failures of governments to live up to the terms of these treaties. By contrast, in Australia the recognition of the existence of aboriginal title prior to settlement by British colonists only emerged in 1992 with a High Court ruling that entrenched the principle in the country’s body of common law (Davies 2003, p. 28). Whatever the case, however, once the general principle of prior indigenous title has been accepted by a state, land claims by Native groups may then be pursued in order to regain or affirm clear ownership in cases where such ownership has not been superseded through recognized legal means, yet practical control of territory has been lost to either government or private interests.

When countries’ legal institutions recognize the existence of Native title in relation to territory where aboriginal control has been superseded, they place demands on governments and other property holders to either extinguish Native title through accepted channels or return control over land and resources to claimants. As with the acknowledgement of Native title, the means of extinguishment has varied greatly between countries. In Canada (Usher 2003, p. 366) and the United States (Hendrix 2005, p. 764), negotiated agreements (treaties) between governments and aboriginal groups have been the typical
means of title extinguishment. However, in Australia the existence of freehold property resulting from government land alienation schemes developed in the late nineteenth and early twentieth centuries is recognized in that country’s body of law as an adequate means of extinguishment (Davies 2003, p. 28). As uneven as the approaches are, once title is said to be extinguished, governments consider claims to be settled and no further action can be pursued by claimants in relation to questions of ownership.

The principal means of modern title extinguishment, and thus the main outcome of modern land claims negotiations, has been the negotiation of durable and comprehensive treaties. While often focused on the return of land and resources to aboriginal control, treaties are not marked by this feature alone. As land claims launched by aboriginal peoples against modern nation-states often involve territory that is occupied by cities or other intensive and permanent land use, the return of land can be extremely problematic. In such cases, or in cases where two or more groups launch overlapping claims, negotiated settlements between Native groups and governments often include monetary compensation in lieu of returned territory. Further, issues of tax status, education and health provision, and linkage (social, political, economic) with non-Native territories are also frequently addressed in the negotiation of treaties. As Usher notes (2003, p. 379), in Canada treaty negotiations are increasingly marked by a concern with providing claimants with the opportunity to build governance and management capacity through education and partnership. Thus, far from simply serving to settle land and resource disputes between indigenous and settler populations, the treaties that result from land claim negotiations are often required to address the social, political, and economic marginalization of Native populations that has arisen out of colonial situations.

While land claims hold out the possibility of transforming the material (and therefore social) conditions of life for aboriginal peoples in the former settler colonies of the world, they also, as Hendrix argues, provide a possible means through which the historical and geographical memories of settler populations might be reworked. The dominant narratives of American and Australian settlement treat the period prior to European contact as prehistoric; the lands were empty and awaiting improvement by industrious hands, so goes the story. By successfully reclaiming land and resources through resort to the institutions put in place by colonial societies, however, Native peoples across the world are taking back ownership of more than territory. Insisting upon official recognition of precontact occupancy and title, marginalized cultures are writing themselves back into history and, therefore, into the fabric of modern nation-states.

LAND REFORM

The term land reform refers principally to the redistribution of agricultural land from existing private or public landowners to tenant farmers, agricultural laborers, or collective farmers who work on such land without owning it. The absence of ownership or equivalent secure rights to land carries numerous negative consequences. These include lack of ability, or motivation, to invest in the land; stagnant agricultural productivity; rural poverty and malnutrition; lack of status and power for the landless; pressures to flee rural poverty for ill-equipped cities; land degradation; and a dearth of rural families with assets or savings.

By contrast, successful redistributive land reform can confer broad benefits, including increased crop production and improved nutrition, reduction of rural poverty, greater grassroots empowerment and a lessening of social unrest, reduced pressure for urban migration, better envi-
Land Reform

Widespread positive results from redistributive land reforms have been experienced by well over a billion people since World War II ended in 1945. While land reform is not a panacea against rural poverty, it has been a foundational element for effective economic and social development in many settings. Fully a billion others are potential future beneficiaries.

This entry begins with a brief historical perspective, then looks at major post–World War II land reforms, followed by some key program-design considerations, a review of where land reform remains relevant today, and the broader economic, social, and political issues likely to influence decisions about undertaking future land-reform programs.

HISTORY

Documented land reforms occurred in ancient Greece in the sixth century BCE and Republican Rome in the second century BCE. Perhaps reminding us how controversial land reform can be if not adequately designed or explained, the brothers Gracchi successive tribunes or leaders of the Republic, were assassinated, largely because of their support for redistributive land reform. There is also an Old Testament reference to the requirement of land redistribution every fiftieth year, in the “year of the jubilee” (Leviticus 25:23), although scholars are unsure of the extent of actual implementation.

A major land reform was carried out around the beginning of the French Revolution (1789), after which the reasonably satisfied French peasantry largely sat out the (mostly urban) violence and upheaval. About the same time, a democratic and nonviolent land reform began in Denmark.

A variety of land-reform undertakings are found in nineteenth-century Europe. Notable among them was the emancipation of the Russian serfs by Czar Alexander II (1818–1881) in 1861, accompanied by a major distribution of land (however, heavy repayment obligations were imposed on the land recipients). While President Abraham Lincoln (1809–1865) emancipated the slaves in 1863 in the midst of the Civil War in the United States, this was unfortunately not followed by redistribution to the freed slaves of the southern plantation lands on which they had worked: Most were left socially and economically disempowered, many working as sharecroppers with insecure tenure and paying high rents on the same lands on which they had worked as slaves.

The twentieth century before World War II saw a number of democratic and nonviolent land reforms, including many in European countries, as well as several violent civil upheavals that were significantly fueled by the grievances of landless or near-landless peasants. The Mexican peasantry supported a revolution (1910) and fought a subsequent civil war, eventually receiving perpetual land rights beginning in the 1930s. The Russian peasantry, still land-hungry, supported the 1917 revolution and received land, but later were forced to turn that land over to collective farms (1930s). A weak republican government in Spain made indecisive efforts to redistribute land in the 1930s, ultimately collapsing before the catalyzing acts of peasants who wanted land and seized it, and large landowners and their allies who feared communism or anarchy, and helped foment a successful military rebellion (the 1936–1939 Spanish Civil War).

POST–WORLD WAR II

There have been three principal waves of land reform since 1945. The first, during the decade following World War II, occurred largely where the war had catalyzed or helped speed regime change.

Leading examples were land-to-the-tiller programs in Japan, Taiwan, and South Korea—with tenant farmers receiving ownership of the same land on which they had been tenants—carried out under U.S.-supported non-communist regimes. In mainland China, the Communists conducted a similar reform (but accompanied by anti-landlord violence) when they took power in 1949, but this was followed by forced collectivization of all farmland in the mid-1950s. This period also included involuntary collectivizations carried out by Eastern European communist regimes that were within the Soviet sphere—even though the great majority of affected farmers had already been individual owners. Poland was a notable holdout, maintaining its system of small owner-operated farms.

A second wave of land-reform efforts occurred as many countries gained independence from colonial powers from the late 1940s onward. But most of these reforms were poorly designed and had little impact. The handful of successes—mainly land-to-the-tiller programs—included a few Indian states (each state legislates its own land-reform rules), notably West Bengal and Kerala in the 1970s and 1980s, and also included South Vietnam, under the threat of a communist insurgency, during the 1970–1973 period.

Also of importance during this time were programs taking large estates for redistribution to farm laborers, continuing in postwar Mexico, going forward in 1950s Bolivia, and undertaken in 1980s El Salvador, the latter again under the threat of a communist insurgency. The El Salvador reform also included a land-to-the-tiller program for tenant farmers.

There were also many failures during this period. These included other Latin American attempts, chiefly involving large estates, such as occurred in Brazil,
Colombia, and (reversed through the 1954 U.S.-sponsored overthrow of the regime) Guatemala. Failures in Asia, mostly attempts to redistribute tenanted land or above-"ceiling" land, included most Indian states, Pakistan, Bangladesh, Indonesia, and the Philippines, among others. In Africa, where land-redistribution efforts have centered on regions of white-owned estate land, many programs have shown slow progress (South Africa) or gone far astray (Zimbabwe, apparently benefiting largely the president's cronies and militia, while evicting most farm laborers).

One impetus to land reforms that has largely disappeared with the demise of militant Marxist ideology was the threat of communist insurgency built upon the promise of land, which led both to revolutionary land reforms (Russia, China, Cuba, Nicaragua, Vietnam) and to protective, anticomunist land reforms (South Vietnam, El Salvador). But some such insurgent movements persist (the Naxalites in eastern India, the New People's Army in the Philippines), and extralegal efforts to occupy large estates, though well short of armed insurgency, are still found in countries like Brazil.

The latest wave of postwar land reform has involved efforts to break up the large collective farms that existed under many communist regimes (decollectivization) and to give ownership or equivalent secure individual land rights to the former collective-farm workers (privatization). Progress has varied on these two aspects: China was the first to decollectivize (1979–1983) but has only partially privatized the resulting individual farms; Vietnam has now done both, as have most (but not all) Eastern European countries; Russia and Ukraine have formally privatized, but the former collectives remain the major operating units, usually renting in from their workers the individual land rights those workers have received. Finally, some countries, such as North Korea and Cuba, have neither broken up the collectives nor given individual land rights. Where physical breakup has occurred, it has generally affected cropland, but left grazing land as commons lands available for joint use.

**PROGRAM DESIGN**

Accumulated land-reform experience indicates numerous features of program design, subject to deliberate change, which can play an important role in determining success or failure. Three features of continuing importance are discussed below.

First, will “full-size” farms, or something much smaller, be the goal? If a full-size farm by local standards, say two to three acres, is to be allocated, then multiplying this size farm by the number of households needing land often indicates that 20 to 40 percent of the country's cropland will have to be taken and redistributed. In most temporary settings, such a program is politically and financially impractical.

Thus, it is important that recent research in many countries, such as India, now indicates that the “benefits curve” rises extremely rapidly with the first few thousand square feet of land distributed. In particular, distributing a homestead plot of one-tenth acre or even less, to supplement the farm's existing livelihood, not only affords room to erect a small house, but beyond that allows an area for intense cultivation and for keeping one or two animals. This results in substantial increments to that family's nutrition, income, and status. Yet distribution of such homestead plots to nearly all the landless may require only 1 percent or less of the country's cropland, changing judgments as to political and financial feasibility—as currently in India—in a dramatically favorable way. The disproportionately large contribution of small plots to agricultural production has also been seen in many collective-farming systems where the workers were permitted to have “private plots” near their homes for personal cultivation, as well as in the “garden plots” that many of these countries have allowed urban households to maintain on the peri-urban fringe.

Second, will the land reform be heavily publicized? China's program to give former collective (now individual) farmers secure, long-term rights exemplifies the impact of publicity. An earlier, 1998 law was widely publicized, and achieved over 40 percent effective implementation by mid-2001. A later, 2002 law, although providing even stronger rights to the farmers, received little publicity, and by mid-2005 achieved only minimal additional implementation among farmers unaware of their rights.

Finally, will beneficiaries receive support, such as technical advice and farm credit? While wide agreement exists that this is desirable, there remains disagreement as to how vital it may be in particular settings. It would be rare, however, that an otherwise-feasible land redistribution should be delayed because such complementary programs were not yet available.

Still another measure might be noted, one that has stirred considerable recent debate. That is the impact of giving confirmatory land-rights documents (titles) to those already in reasonably uncontested possession of land (by contrast, there is little question that beneficiaries of redistribution of land that had been privately owned by someone else, such as tenants receiving the land of former landlords, or agricultural laborers receiving the land of former plantation owners, should receive confirmatory documentation). The issue as to titling those in already-existing uncontested, but undocumented, possession is more complex than may be immediately evident. Some customary or traditional land rights may exist as distinct elements or layers that may be difficult to separately
describe and document; some may be held by groups rather than individuals; and in some settings those who actually hold the rights may be preempted (through corruption or chicanery) by false claimants when a documentation process occurs. The benefits of giving documentation to uncontested existing possessors appear to be situational, emerging most clearly in urban settings.

CURRENT NEEDS
The two most populous developing countries at the beginning of the twenty-first century, China and India, are also the two most critical arenas for further land reform measures. Both countries have already adopted the essential laws, but both need to move to much wider implementation. In China’s case, such efforts would involve renewed publicity and expanded formal documentation for farmers’ long-term land rights. In India, the central government needs to help finance, and the individual states need both to finance and implement, a widespread homestead-plot program.

There are many additional settings where land reform efforts could have a major impact. Homestead-plot programs, for example, hold important potential in Indonesia, Pakistan, and Bangladesh, and in a number of other Asian, African, and Latin American countries with significant numbers of landless poor. And, in some settings, unused or underutilized land in large estates may still be sufficient in quantity and cheap enough in price to provide full-size farms to many of the rural poor. And, in some settings, unused or underutilized land in large estates may still be sufficient in quantity and cheap enough in price to provide full-size farms to many of the rural poor. For example, in Brazil and further significant parts of Latin America, as well as in some parts of Africa with large-farm colonial legacies.

Also, communist or formerly communist countries that have not yet done so must eventually confront the twin tasks of decollectivizing and privatizing their inefficient and low-productivity collective-farm sectors, among them North Korea and Cuba. Others, like Russia and Ukraine, which have formally privatized, will have to facilitate the actual breakup of the large farms.

Altogether, the remaining potential for land reform is at least as great as what was carried out globally during the six decades after World War II.

BROADER ECONOMIC, SOCIAL, AND POLITICAL ISSUES
Every land reform, no matter how well designed, has to take account of broader economic, social, and political challenges and issues in the particular country.

Economic Issues Land reform neither creates nor destroys land: It simply puts an existing population into a relationship with an existing agricultural land base that is likely to be fairer and more productive than the present one. One consideration is that the accumulated evidence now indicates that small farms are, in terms of total factor productivity (that is, with regard to the value of land, capital, and labor inputs), generally more productive than larger farms in less-developed-country settings. Such countries are typically short on land, short on capital, and long on labor. Hence it makes good economic sense to have many motivated families—and ownership provides crucial motivation—applying family labor intensively on small farms while using as little capital (machinery, pesticides, etc.) as possible to achieve a given production result.

A related economic point on which there is general agreement is that large farms with a large number of laborers working together—such as most plantations or collective farms—are generally inefficient, because of the great difficulty of supervising labor on these far-flung operations with their complex and variable sequences of tasks.

A further economic point: Viable land reform in the transitional (communist or formerly communist) societies entails no land costs, since the land to be redistributed is presently publicly owned. And improved design will greatly reduce total land costs in traditional developing-country settings, wherever policymakers opt for a program based on homestead plots rather than full-size farms.

A final economic point, applicable in both traditional land-reform settings and those of the transitional societies, is whether recipients of individual land rights should be restricted in selling or leasing those rights, and if there are such restrictions, how broad should they be and how long should they last? There is disagreement on these issues: Such restrictions may improvidently prevent the creation of wealth in the hands of land-reform beneficiaries, but they may also forestall hasty sales at a low price or leases having adverse terms. Restrictions that are temporary and narrower (e.g., no land sales to foreigners or no large accumulations of land) may be easier to justify than long-term and broad restrictions, which may also be widely ignored and eventually abandoned (as in Mexico).

Social Issues This entry noted above some of the likely consequences of successful redistributive land reform. There are also broader social consequences that are likely for the newly landowning families, such as reduced infant and child mortality resulting from better nutrition; the affordability of increased school-going, including for girls; and increased participation in community affairs for those with the status of “landowner.”

Political Issues To communicate the economic and social case for land reform is, in many settings, to move considerably toward achieving the necessary political support.
Three additional factors, important to what is sometimes called "democratic land reform," are likely to bolster such political support: (1) acquiring any privately held land needed for the land reform on the land market through voluntary sales, or (if the acquisition is involuntary) paying a fair and reasonable price; (2) coupled with this, treating any acquisition of privately held land simply as something needed for a higher social purpose (like land needed for a hospital), not as a judgment that landlords are bad; and (3) giving the beneficiaries a free choice as to how they wish to organize their farming.

LANDLORDS

A landlord is a person or organization that rents out real estate, holding the rights to receive the rentals paid by tenants. Usually a landlord has a freehold estate, a legal right to the possession of, and income from, real estate. A landlord can also be a tenant who subleases the premises to another tenant. A lease divides the estate into a leased fee estate for the owner and a leasehold estate for the renter, the latter providing rights of possession, as laid out in the lease, for a specified duration. If the lease expires and the tenant continues to have possession, he has a tenancy at sufferance.

“Land” in this context includes all space that can be controlled, including territory with water and in the atmosphere, and “real estate” consists of the land and the objects attached to the land, the rest being movable property. Land that is common property, such as the oceans beyond the jurisdiction of governments, are rent free, although international organizations and international law can be considered landlords if they can enforce their authority.

HISTORY OF LAND TENURE

“Land tenure” is the pattern of land ownership. In some small-group societies, the community as a whole often owns territory. The land can either have open access by anyone, or be allocated to families for use, but without inheritance. In some cases, an individual or family has periodic access to lands forming the commons of a village, and families have access to the commons for hunting, fishing, and gathering. Some societies provide priority rights to land when a member makes improvements on the site.

Social scientists such as Franz Oppenheimer have theorized that such land tenure changed mostly because of conquest, as the conquerors became the landlords and the original inhabitants became tenant farmers. In Europe after the collapse of the Roman Empire, the feudal system took hold, where serfs became attached to the land held by the aristocracy.

As trade became more widespread, land became more of a commodity that could be exchanged and operated by landlords for profit rather than for governing power. This change was facilitated in the United Kingdom by the “enclosure” movement, in which the aristocracy took over land that had been held collectively by village residents. The landlords switched much of the enclosed land from farming to raising sheep, and the expelled villagers had to move to cities where they became vagabonds and beggars, some of whom suffered from hunger and illness. Eventually, many became “proletarians” who had little choice but to work for the emerging Industrial Revolution for low wages.

Modern markets for the sale and rental of real estate and of mortgages on real estate are based on having secure and transferable titles to real estate, including the ability to verify a deed to real property. A governmental cadastre or registry of deeds and titles of ownership of estates in

INTRODUCTION
land facilitates the real estate market. During the Middle Ages in Europe, manorial court rolls recorded the titleholders and descriptions of the landholdings. As land became more marketable, the registration of deeds by governments developed to facilitate loans and transactions. In the United States, the recording of titles is the responsibility of the states, usually implemented at the county level. In the United Kingdom, governmental registration of land titles was not fully developed until the twentieth century with the Land Registration Acts of 1925 and 2002.

In his book *The Mystery of Capital*, Peruvian economist Hernando de Soto has emphasized that the absence of land titles has hampered economic development, as squatters avoid building improvements when they fear that their investment may be confiscated. Societies with communal or governmental land can obtain similar security with long-term (e.g., ninety-nine-year) transferable leaseholds.

In Latin America, the Spanish and Portuguese seized land from the Indians and turned the native population into tenants working on large estates, the “latifundia,” as well as working small plots of land for their subsistence. In the southern states of the United States, the Indians were mostly expelled, and plantations utilized slaves imported from Africa.

Although Americans commonly think of the frontier as having been settled by homesteading, most of the western lands were not settled that way but were granted to various special interests such as the railroads, veterans, land-grant colleges, and speculators. As Henry George (1871) described, much land was obtained through dishonest means, such as by fraudulent titles. In California, the Southern Pacific Railroad became the largest landlord, giving the company great political clout.

In continental Europe, the aristocracy continued to own much of the land after the end of feudalism. In Germany, the Prussian aristocrats, called Junkers, owned half the land. In Russia, where the aristocracy remained landlords after the serfs were legally freed, revolution gained popular support with the slogan, “land and liberty,” as popular movements for liberation have recognized a close relationship between liberty and landownership.

In the United States, some two-thirds of the people live in owner-occupied homes, but commercial and industrial land value remains highly concentrated. Landowners and real estate interests have great political clout, which they maintain with significant contributions to political campaigns. As a result, landowners obtain great tax benefits relative to those from other property and sources of income.

The tax benefits of real estate owners include being able to deduct mortgage interest and property taxes from taxable income and to exchange rental properties while deferring payment of capital gains taxes. Further, owner-occupants have a large capital-gains exemption, and in most places, they enjoy a rather light property tax on their land value relative to the civic benefits that raise their land values and rentals.

**LANDLORDISM**

The term *landlordism* is used in sociology and anthropology to refer to land tenure and status relationships with three characteristics: The land tenure is extremely unequal, the landlords tend to be renters who receive rent but do not actively manage their lands, and the landowning class controls and benefits most from the government.

The most stark examples of landlordism are the landed aristocracy and the large landed estates, as in Latin America, but most economies today have significant landlordism. Landlords of dilapidated buildings in blighted areas are disparagingly called “slumlords.”

Since the supply of land is fixed, as the population and wealth grow, a rising demand for land increases rentals and land prices. Much of the gains from increased productivity flow to the landowners as rent and site values. Land value is enhanced even more by public works. The political clout of landowners induces government to place much of the tax burden on labor and enterprise, thus implicitly subsidizing landownership. Landlordism is thus endemic in most economies today, even if it is not as obvious as in the more visible form of a landed agricultural aristocracy.

Some governments have enacted rent control in order to set a maximum rental paid by tenants. Such price controls create shortages of rental units and can discourage maintenance.

In developing countries, prevailing landlordism has induced movements for land reform, a change in land tenure to a more widespread ownership of land. Land reformers have usually advocated a redivision of the land by splitting up large estates. In some cases, the “reform” has granted land to the politically well connected and to inefficient farmers. An effective way to accomplish land reform is by taxing the land value, which then induces the large holders who are not using their land efficiently to sell their land, thus accomplishing redistribution with greater productivity. This policy was implemented to some degree by Japan in the latter 1800s and Taiwan after 1950.

**LANDLORD–TENANT LAW AND RELATIONSHIPS**

The landlord–tenant relationship is governed by private law as set by the lease and by governmental law regarding landlording. A lease is a contract of tenancy, which trans-
fers some of the rights of possession from the landlord as lessor to the tenant as lessee. A tenant has the right of quiet enjoyment, meaning an un molested, tranquil use, free from interference or disturbance. However, the landlord retains the right of entry either with advance notice or in an emergency. Upon the expiration of the lease, the landlord is entitled to reversion, that is, to retake possession.

The lease provides an implied if not explicit warranty of habitability that requires the landlord to maintain the premises in a reasonably safe condition, but tenants can be held liable for the damage they cause. Usually the landlord pays the property taxes, but in a gross lease, usually for commercial real estate, the tenant pays the gross costs of occupancy, including real property taxes, utilities, insurance, and operating expenses. For residential leases, the landlord usually does the maintenance and pays the taxes and insurance, although tenants pay for any renters’ insurance on their personal property.

The lease can specify a fixed time interval of tenancy, or go from month to month. If there is no written lease or no specified time, the relationship is a tenancy at will, subject to termination by the landlord or the tenant at any time. If the tenant remains after the expiration of a lease, the tenant remains liable for the rent. Governmental law limits the power of a landlord to choose a tenant. In the United States, the Civil Rights Act of 1968 prohibits discrimination in housing based on national origin, race, religion, or color. In 1974, sex or gender discrimination was added. The 1988 Fair Housing Act extended antidiscrimination protection to familial status. The Americans with Disabilities Act prohibits discrimination that denies the equal use of property due to physical or mental disabilities. State laws can duplicate or extend the application of antidiscrimination law; for example, the California Fair Housing Laws prohibit discrimination based on sex, color, race, religion, marital status, ancestry, or national origin.

Tenants can exploit landlords as well by causing damage and taking advantage of laws that delay eviction. Landlords can protect themselves by screening tenants in legal ways, by visiting where they live, observing the condition of their car, asking parents of young tenants to cosign leases, making tenants responsible for minor repairs, and providing a discount for prompt payments of rental (which is better psychologically than fines for late payment).

Landlords in the United States are also vulnerable to civil asset forfeiture, that is, the confiscation of their property if the police suspect that there is illegal drug activity on the premises, even if the landlord is not aware of it. While large-scale landowners and developers typically have political clout, they sometimes use their political power at the expense of other real estate owners, such as when a government uses eminent domain to forcibly take real estate from some owners and transfer it to private developers, a practice that was widely reported in Kelo v. City of New London (2005). The Supreme Court’s decision alarmed many property owners, who feared the case would facilitate more real estate “takings” by governments, and some states have enacted laws limiting such wide powers of eminent domain.

LANDLORDS, ABSENTEE

The term “absentee landlord” describes the situation where a person with the ultimate ownership of land—and this may be an actual person, a corporate entity, or even the state itself—does not personally use the land but instead extracts payment for its use by another. In one sense most landlords are “absent” in that the land is let for a rent to another person who enjoys physical possession and use of it, but an “absentee landlord” is a more pejorative description. It is meant to signify a landowner whose only interest in the land is to extract its economic value and who pays little or no regard to the state of the land or the welfare—economic, social, or political—of the person who is paying the rent. Such landlords are “absent” both in the sense that they have little or no social, emotional, or physical attachment to the land, and also because in many cases they are physically distant from the land, preferring either to regard the land as if it were merely an entry on a profit and loss account or, in some cases, to appoint a more local agent who will manage the land for the landlord on a purely commercial basis.

Historically absentee landlords have generated both social and economic problems on a grand scale, especially when the absenteeism is allied with external domination.
of the local territory. The Protestant owners of lands in Catholic Ireland in the seventeenth century and the mainly English absentee landowners of Prince Edward Island, Canada, in the eighteenth century are well-known examples of how absentee ownership can go hand in hand with “colonial” dominance, but this is not merely an historical problem. Absentee owners of Scottish Highland sporting estates; anonymous state control of land in less developed countries; corporate investors (e.g., pension funds) in city center business districts; absentee owners of Midwestern agribusinesses in the United States; and absent landlords of low-quality, deteriorating residential properties in most of our major cities are just a few examples from the twenty-first century.

Absentee landlords are perceived to be a threat to the economic and social viability of communities. By extracting value from the land (rent) but not spending or reinvesting in the local community, absentee landlords produce an outward flow of economic capital. They drain the local community. When accompanied by a constant turnover of short-term tenants, the social capital of a community is diminished and all of those community activities that depend on the interest and commitment of stable residents are lost. Given that absentee landlords may regard the land as merely another form of economic asset, rather than as a social and economic resource for the community in which the land is situated, many absentee landlords observe only the bare minimum of standards in relation to the land and the buildings on it. Properties owned by absentee landlords often are in a poor state of repair and building and zoning controls are either ignored or observed to the minimum standard permitted. An effective local management team can prevent some of the worse excesses, but the geographically absent landlord may be slow to respond to requests from the tenants or the local authorities. In many cases such landlords will simply sidestep calls for repairs or renovations and attempt to avoid local taxation.

Absentee landlords also generate numerous legal problems. Enforcing obligations in letting arrangements, serving of notices for the enforcement of tenants’ rights, and ensuring observance of public rights affecting the property (for example public access routes and rights of way) are common problems. In extreme cases in countries without a systematic register or record of land ownership, it may be difficult to identify who actually is the ultimate owner and this can lead to problems of squatting as well as making the land economically stagnant.

The economic and social cost of absentee landlords can be considerable and many countries or localities have attempted to impose regulatory or legal requirements either in order to curb absenteeism or to remove its harmful effects. These have included public access to land registers in order to identify absent owners, tax incentives for owners who maintain an economic presence in the local community and penal local taxes for those draining the local economy, enhanced procedures for the recovery of land for local landlords when faced with defaulting tenants, compulsory enfranchisement (sale of the land to the tenant) on long leases, and the enhancement of enforcement powers for violators of building codes.

LARGE SAMPLE PROPERTIES

In empirical work, researchers typically use estimators of parameters, test statistics, or predictors to learn about a given feature of an underlying model; these estimators are functions of random variables, and as such are themselves random variables. Data are used to obtain estimates, which are realizations of the corresponding estimators—that is, random variables. Ordinarily, the researcher has available only a single sample of \( n \) observations and obtains a single estimate based on this sample; the researcher then wishes to make inferences about the underlying feature of interest. Inference involves the estimation of a confidence interval, a p-value, or a prediction interval, and it requires knowledge about the sampling distribution of the estimator that has been used.

In a small number of cases, exact distributions of estimators can be derived for a given sample size \( n \). For example, in the classical linear regression model, if errors are assumed to be identically, independently, and normally distributed, ordinary least squares estimators of the intercept and slope parameters can be shown to be normally distributed with variance that depends on the variance of the error terms, which can be estimated by the sample variance of the estimated residuals. In most cases, however, exact results for the sampling distributions of estimators with a finite sample are unavailable; examples include maximum likelihood estimators and most nonparametric estimators.

Large sample, or asymptotic, properties of estimators often provide useful approximations of sampling distributions of estimators that can be reliably used for inference-making purposes. Consider an estimator

\[
\hat{\theta}_n = g(Y_1, \ldots, Y_n)
\]
of some quantity $\theta$. The subscript $n$ denotes the fact that $\hat{\theta}_n$ is a function of the $n$ random variables $Y_1, \ldots, Y_n$; this suggests an infinite sequence of estimators for $n = 1, 2, \ldots$, each based on a different sample size. The large sample properties of an estimator $\hat{\theta}_n$ determine the limiting behavior of the sequence $\{\hat{\theta}_n \mid n = 1, 2, \ldots\}$ as $n$ goes to infinity, denoted $n \to \infty$. Although the distribution of $\hat{\theta}_n$ may be unknown for finite $n$, it is often possible to derive the limiting distribution of $\hat{\theta}_n$ as $n \to \infty$. The limiting distribution can then be used as an approximation to the distribution of $\hat{\theta}_n$ when $n$ is finite in order to estimate, for example, confidence intervals. The practical usefulness of this approach depends on how closely the limiting, asymptotic distribution of $\hat{\theta}_n$ approximates the finite-sample distribution of the estimator for a given, finite sample size $n$. This depends, in part, on the rate at which the distribution of $\hat{\theta}_n$ converges to the limiting distribution, which is related to the rate at which $\hat{\theta}_n$ converges to $\theta$.

**CONSISTENCY**

The most fundamental property that an estimator might possess is that of consistency. If an estimator is consistent, then more data will be informative; but if an estimator is inconsistent, then in general even an arbitrarily large amount of data will offer no guarantee of obtaining an estimate “close” to the unknown $\theta$. Lacking consistency, there is little reason to consider what other properties the estimator might have, nor is there typically any reason to use such an estimator.

An estimator $\hat{\theta}_n$ of $\theta$ is said to be weakly consistent if the estimator converges in probability, denoted

\[ \hat{\theta}_n \xrightarrow{p} \theta \]

This occurs whenever

\[ \lim_{n \to \infty} P(|\hat{\theta}_n - \theta| < \varepsilon) = 1 \]

for any $\varepsilon > 0$. Other, stronger types of consistency have also been defined, as outlined by Robert J. Serfling in *Approximation Theorems of Mathematical Statistics* (1980). Convergence in probability means that, for any arbitrarily small (but strictly positive) $\varepsilon$, the probability of obtaining an estimate different from $\theta$ by more than $\varepsilon$ in either direction tends to 0 as $n \to \infty$.

Note that weak consistency does not mean that it is impossible to obtain an estimate very different from $\theta$ using a consistent estimator with a very large sample size. Rather, consistency is an asymptotic, large sample property; it only describes what happens in the limit. Although consistency is a fundamental property, it is also a minimal property in this sense. Depending on the rate, or speed, with which $\hat{\theta}_n$ converges to $\theta$, a particular sample size may or may not offer much hope of obtaining an accurate, useful estimate.

A sequence of random variables $\{\hat{\theta}_n \mid n = 1, 2, \ldots\}$ with distribution functions $F_n$ is said to converge in distribution to a random variable $\theta$ with distribution function $F$ if, for any $\varepsilon > 0$, there exists an integer $n_0 = n_0(\varepsilon)$ such that at every point of continuity $t$ of $F$, $|F_n(t) - F(t)| < \varepsilon$ for all $n \geq n_0$. Convergence in probability implies convergence in distribution, which is denoted by $\hat{\theta}_n \xrightarrow{d} \theta$.

Often, weakly consistent estimators that can be written as scaled sums of random variables have distributions that converge to a normal distribution. The Lindeberg-Levy Central Limit Theorem establishes such a result for the sample mean: If $Y_1, Y_2, \ldots, Y_n$ are independent draws from a population with mean $\mu$ and finite variance $\sigma^2$, then the sample mean

\[ \bar{Y}_n = n^{-1} \sum_{i=1}^{n} Y_i \]

may be used to estimate $\mu$, and

\[ \frac{1}{\sigma n^{1/2}} (\bar{Y}_n - \mu) \xrightarrow{d} N(0,1) \]

The factor $n^{1/2}$ is the rate of convergence of the sample mean, and it serves to scale the left-hand side of the above expression so that its limiting distribution, as $n \to \infty$, is stable—in this instance, a standard normal distribution. This result allows one to make inference about the population mean $\mu$—even when the distribution from which the data are drawn is unknown—by taking critical values from the standard normal distribution rather than the often unknown, finite-sample distribution $F_n$.

Standard, parametric estimation problems typically yield estimators that converge in probability at the rate $n^{1/2}$. This provides a familiar benchmark for gauging convergence rates of other estimators. The fact that the sample mean converges at rate $n^{1/2}$ means that fewer observations will typically be needed to obtain statistically meaningful results than would be the case if the convergence rate were slower. However, the quality of the approximation of the finite-sample distribution of a sample mean by the standard normal is determined by features such as skewness or kurtosis of the distribution from which the data are drawn. In fact, the finite sample distribution function $F_n$ (or the density or the characteristic functions) of the sample mean can be written as an asymptotic expansion, revealing how features of the data distribution affect the quality of the normal approximation suggested by the central limit theorem. The best-known of these expansions is the Edgeworth expansion, which yields an expansion of $F_n$ in terms of powers of $n$ and higher moments of the distribution of the data. Among those who explain these principles in detail are Harald Cramér in *Biometrika* (1972), Ole E. Barndorff-Nielsen and David Roxbee Cox in *Inference and... “...
Laspeyre's Index

Many nonparametric estimators converge at rates slower than \( n^{-\frac{1}{2}} \). For example, the Nadarya-Watson kernel estimator (Nadarya 1964; Watson 1964) and the local linear estimator (Fan and Gijbels 1996) of the conditional mean function converge at rate \( n^{-\frac{1}{2}} + d \), where \( d \) is the number of unique explanatory variables (not including interaction terms); hence, even with only one right-hand side variable, these estimators converge at a much slower rate, \( n^{-\frac{1}{2}} \), than typical parametric estimators. Moreover, the rate of convergence becomes slower with increasing dimensionality, a phenomenon often called the curse of dimensionality. Another example is provided by data envelopment analysis (DEA) estimators of technical efficiency; under certain assumptions, including variable returns to scale, these estimators converge at rate \( n^{-\frac{2}{4}d + d} \), where \( d \) is the number of inputs plus the number of outputs. Léopold Simar and Paul W. Wilson discuss this principle in the Journal of Productivity Analysis (2000).

The practical implications of the rate of convergence of an estimator with a convergence rate slower than \( n^{-\frac{1}{2}} \) can be seen by considering how much data would be needed to achieve the same stochastic order of estimation error that one would achieve with a parametric estimator converging at rate \( n^{-\frac{1}{2}} \) while using a given amount of data. For example, consider a bivariate regression problem with \( n = 20 \) observations. Using a nonparametric kernel estimator or a local linear estimator, one would need \( m \) observations to attain the same stochastic order of estimation error that would be achieved with parametric, ordinary least-squares regression; setting \( m^{\frac{1}{2}} = 20^{\frac{1}{2}} \) yields \( m \approx 1,789 \).

The large sample properties of parametric and nonparametric estimators offer an interesting trade-off. Parametric estimators offer fast convergence, therefore it is possible to obtain meaningful estimates with smaller amounts of data than would be required by nonparametric estimators with slower convergence rates. But this is valid only if the parametric model that is estimated is correctly specified; if not, there is specification error, raising the question of whether the parametric estimator is consistent. On the other hand, nonparametric estimators largely avoid the risk of specification error, but often at the cost of slower convergence rates and hence larger data requirements. The convergence rate achieved by a particular estimator determines what might reasonably be considered a “large sample” and whether meaningful estimates might be obtained from a given amount of data.

(1999, pp. 464–465), lists several popular misconceptions concerning the large sample properties of estimators. It is sometimes claimed that the central limit theorem ensures that various distributions converge to a normal distribution in cases where they do not. The Lindeberg-Levy central limit theorem concerns a particular scaled sum of random variables, but only under certain restrictions (e.g., finite variance). Other scaled summations may have different limiting distributions. Spanos notes that there is a central limit theorem for every member of the Levy-Khintchine family of distributions that includes not only the normal Poisson, and Cauchy distributions, but also a set of infinitely divisible distributions. In addition, continuous functions of scaled summations of random variables converge to several well-known distributions, including the chi-square distribution in the case of quadratic functions.

LASSWELL, HAROLD
1902–1978

Harold Lasswell was an influential social scientist who contributed to the field of political science through research on political psychology, quantitative methods, and public policy. Lasswell was born in Donnellson, Illinois, to a schoolteacher and Presbyterian minister. At the age of sixteen, Lasswell received a scholarship to study at the University of Chicago, and he later completed graduate studies at the London School of Economics. Lasswell was a faculty member at the University of Chicago from 1922 to 1938 and at Yale University from 1946 to 1970. Lasswell died in 1978 in New York City.

Lasswell’s approach to political science was behavioral, and he was a part of the “Chicago school” of sociology. The Chicago school was a group of academicians in the 1920s and 1930s who focused on the urban environment, specifically through ethnographic fieldwork and an emphasis on social issues. Lasswell believed that propaganda was a key tool in public policy making, arguing that the citizenry was largely uninformed and often did not understand what was in its best interest. Lasswell was one of the first scholars to define and systematically explore the concept of propaganda, through his book Propaganda Technique in World War I (1927).

Lasswell’s work on propaganda later expanded into a more general research agenda on communication. Lasswell contributed to the field by suggesting that more than one “channel” of media can carry a message. His model of communication is shown through a basic question: “Who says what, in which channel, to whom, and with what effect?” This model identified the several different components of communication in a political sphere: “Who” involved the political body or agency communicating, “what” is the gist of the message or idea, “channel” is the venue of communication, “whom” is the target audience, and “effect” is the policy outcome. His model encouraged systematic thinking about political communication and the psychological and policy implications of different forms of communication. Perhaps Lasswell’s most famous and widely read work is his general treatise on politics, Politics: Who Gets What, When, and How (1936), which is an abridged but more general commentary on his model of communication.

Lasswell’s work shifted in the later stages of his career to more of an emphasis on the policy sciences. Many see him as the father of policy sciences, and his work in that area is certainly among the first and most influential. Lasswell’s research became larger in scope and resulted in policy-making frameworks that were more comprehensive and less concerned with narrow theorizing. Lasswell’s ideas were rooted in his early work on propaganda—actors in the policy process were seen as sometimes irrational and pursuing goals that would ultimately harm them, and this led to a need for policies that went beyond those based in simple rational choice. Lasswell argued that misguided political behavior could easily undermine democracy, and called attention to the need for policymakers to consider both expressed and unexpressed constituent needs.

Lasswell argued that the role of the policy sciences was to produce knowledge for democracy. His emphasis on contextualism influenced quantitative research in important ways, guiding analysts to consider as many external influences as possible in their research. Lasswell believed that the role of the analyst was both scientist and activist—the policy analyst cannot be completely objective in selection of goals, but should work toward objectivity in analysis of results. Although some have cast Lasswell as a positivist, his approach had both positivist and postpositivist themes.

Lasswell’s approach to political science and public policy was met with some criticism. Many disagree with Lasswell’s assertion that citizens often do not understand what they need, finding his approach to be at once paternalistic and naïve. Some also believe that Lasswell’s view of the policy analyst is a romanticized one, exaggerating the impact that the analyst can have on policy making and ignoring issues with using objective data for political decision-making.

LATIFUNDIA
A *latifundium* is a large piece of contiguous land that belongs to a single individual or family. It is a form of property as well as a mode of production that for centuries has determined the socioeconomic structures in many parts of the world, even through to the present day. Historically, latifundia were owned by members of the aristocracy, conferring upon them considerable social and political power and providing them with the income needed to support a lavish lifestyle.

To become the owner of a latifundium did not require much capital. Through ways more or less legal, latifundisti appropriated lands from the public domain and took over the holdings of poor peasants. The size of latifundia varied: from 600 acres in ancient Rome, which guaranteed the owner a senatorial seat, to the estates of Polish magnates extending over 250,000 acres, to those of *hacendados* in Mexico of over half a million. From the beginning, latifundia were commercial enterprises dedicated primarily to growing produce and livestock for profit, both for distant and nearby urban markets. In *On Agriculture*, Cato the Elder (234–149 BCE) emphasized the importance of latifundia being located near good roads and waterways so as to get the crops to their markets. All later forms of latifundia—haciendas, plantations, and Balkan *chiflakes*—followed the same model and reproduced the same form of class domination: a paternalistic landlord ruling over a mass of laborers—slaves, landless peasants, manorial serfs, or peons. Latifundisti maintained political control in the provinces as well, despite being absentee landlords who resided in urban centers and left management of their estates to *villici*, or hired administrators.

The term *latifundium* is synonymous with other terms commonly used for large estate systems: Russia’s *pomiestny*, Prussia’s *Junkerdom*, Poland’s magnate estate, and Latin America’s hacienda (*fazenda* in Brazil, *estancia* in Argentina, *fundo* in Chile, *finca* in Bolivia and Peru). The term itself carries with it a wide range of negative connotations that comprise what may be called a “black legend.” Ancestors of slave plantations, the ancient Roman latifundia have been described as the model for imperialism, colonialism, and modern slavery. A latifundista was a landlord who monopolized huge tracts of land, much of which he left fallow “by virtue of idleness.” The system has been blamed for hindering modernization, preventing social mobility and the rise of the middle classes, making a few people very rich and bringing dire misery to the many, and finally for destroying the peasantry and unraveling rural society. The black legend was famously summed up by Pliny the Elder (23–79 CE) as *latifundia perdidere Italiam*, causing the ruin of Rome, together with its provinces—Egypt, North Africa, Gaul, Spain, and Sicily.

Latifundia were originally a Roman phenomenon. There were no large landholding fortunes before then, neither in ancient Greece nor in the early Roman republic, where laws systematically restricted the size of a family’s property (the average farm was four acres). Extensive holdings first appeared in the fourth century BCE when Rome converted part of its newly conquered territory in Italy into state domain and then rented it out to wealthy people. These first latifundia, some 1,000 acres in size, became common in Etruria and southern Italy. Wars with Carthage further enriched a Roman patriciate who—excluded from trade and commerce—invested their war booty into large latifundia so as to make profits along capitalistic lines.

Prolonged warfare and centuries of conquest eventually concentrated the land in the hands of a few and pushed small peasants off the land. Before long, the city of Rome was overrun with dispossessed paupers.

By 23 BCE the newly formed Roman Empire was one hundred times larger than the republic had been at the time of the Punic Wars, and latifundisti were cultivating the soil of their immense estates with armies of slaves. In Nero’s time (37–68 CE), Pliny tells us, half the land of the North African province was divided up among six patricians and organized in huge latifundia farmed by slaves and native peasants. “Life on the great estate,” splendidly illustrated in mid-second-century mosaics in Tunisia, became a popular art genre. But it was an ultimately oppressive system that gave rise to slave revolts, like the one famously led by Spartacus in 73 to 71 BCE.

In the final years of the Roman Empire, these slave workers were replaced by *coloni*, small tenant farmers who became permanently attached to the estates (*glebae adscripti*) and evolved eventually into feudal serfs. Latifundia persisted in Italy, Gaul, Spain, southern Britain, along the Rhine, and in the eastern Byzantine Empire for centuries after the fall of Rome; in Sicily they survived until the 1950s. Even if, after the German invasions, a new class of landowners began to emerge as different groups adapted the Roman agrarian system to their particular needs, there still existed considerable continuity over the centuries, from the Roman latifundium and its slaves to the manor and its serfs.

The conquest of the Americas and the expansion of the world economy in the sixteenth century created ideal conditions for exporting the European manorial system. While vast commercial estates emerged in the New World, agrarian capitalism also began to flourish throughout most of Europe.

Beyond the Elbe River, for example, and in the eastern part of the Austrian Empire, feudal lords transformed...
their large properties into Gutsherrschaften. In Poland, especially in the Ukraine and Lithuania, immense lands and power became increasingly concentrated in the hands of the magnates. In Spain, the south was turned into large latifundia, established on formerly Moorish land (they had virtually abolished the manor system). All these market- and profit-oriented latifundia were farmed by peasant-serfs through a system of compulsory labor.

There were no market economies or commercial estates in the New World before the Europeans arrived and only the merest hint of a landed aristocracy in the Aztec and Incan empires. The profit-oriented latifundia system came with the colonists, and it carefully reproduced the European model. With few exceptions, the haciendas traced their origins to the sixteenth century, when viceroys divided up the Indians and the land (encomiendas) among the conquerors. In time, with a minimum outlay of capital, encomenderos became latifundisti (hacendados), the Indians became their peons, and the latifundium (hacienda) the most highly visible social and economic institution of the countryside.

The traditional monolithic model of the Latin American latifundium emphasized its continuity with late-medieval Spain. The landowner had aristocratic pretensions and displayed ostentatious patterns of consumption. He tied the laborers to the estate through debt peonage, built his great house to resemble a fortress, made the estate self-sufficient, and paid lip service to a kind of unproductive mentality. This “feudal” representation of the latifundium was challenged by dependency theorist André Gunder Frank (1929–2005), among others, who saw the latifundia as actively engaged in capitalist modes of production and the world market. Similarly, the North American plantation system, based on African slave labor, must be seen as a capitalist enterprise.

Similar patterns existed in Asia as well. In the Philippines, for example, Spanish latifundia were established on the land of Dominican friars and were farmed by Tagalog and Chinese laborers who were relieved of their “public corvées” to sustain the priests’ cash-crop-enterprise. In Vietnam, latifundia arrived with the French, who wanted to turn the colony into a major exporter of agricultural products. In India, it was the British who established an abusive and irresponsible absentee landowner system. Only in China had the system existed independently for centuries, until the 1600s, when it gave way to tenancy.

By the eighteenth century, latifundia dominated the life of the world’s rural peripheries. Associated with serfdom and debt-peonage, the institution came under harsh criticism from scholars and bureaucrats who espoused physiocratic doctrines, while estates were the target of violent peasant attacks.

Despite calls for change, nearly all agricultural production for the world market was still controlled by latifundia in the nineteenth century, and the concentration of land had significantly increased. In Bohemia, Hungary, the Balkans, Poland, Germany, Ireland, Chile, and Mexico, more than half of the land belonged to large estates, some of which achieved truly princely dimensions. The secularization and subsequent sale of ecclesiastical property gave rise to new latifundia in southern Italy and Spain, as well as in Latin America. Many economists saw small-scale farming as economically wasteful, and even some social democrats like Karl Kautsky (1854–1938) argued in favor of the modern latifundium.

The nineteenth-century latifundia system survived the abolition of slavery and serfdom, replacing them with various contractual arrangements and modes of labor control. Junker land was now being cultivated by day laborers and seasonal Slavic workers. While the Balkan chifilks were regulated by the bailiff system, the system of rent-racking (landlords raising rents exorbitantly upon expiration of leases) in Ireland did not change at all.

The development of industrial capitalism in Europe created new market conditions and new possibilities for agrarian systems in Latin America—a development that political independence from the Old World only served to promote. Coffee, cereal, and sugar plantations expanded, these often owned by Creoles and mestizos. Latifundia also expanded exponentially following the confiscation and sale of the vast holdings of the Catholic Church. And finally, as the nonrural sectors declined during the Latin American wars of independence, latifundisti gained an unprecedented degree of political power, often running their own private regional states. Not only did they control the conservative parties and the military, but they often had the support of the liberals as well.

As new market opportunities opened up in the nineteenth century, latifundisti moved effortlessly with the times, acquiring credit from banks to purchase more land and expand the number of laborers. Their ways of operating were neither “traditional” nor “modern,” neither feudal nor capitalist, as can be seen by the example of the Fascist latifundium system in southern Italy.

This new commercial growth was accompanied by the emergence of an impoverished and embattled landless proletariat. Their plight placed latifundia, once again, at the center of the so-called agrarian question. Circa 1900, latifundisti still owned and cultivated one-fourth of the total agricultural land of Germany and half of the arable land of Romania and Hungary, employing a full one-third of the population (six million workers) in this latter country. It was then that peasant movements and progressive parties joined forces to declare war on the latifundia, calling for the expropriation of vast tracts of land. Following
World War I (1914–1918), the old order seemed doomed (at least in Europe and Mexico), and national agrarian reforms began expropriating land belonging to absentee owners and corporations.

The last vestiges of latifundism definitively vanished from Europe in the second half of the twentieth century, while still maintaining a toehold as late as the 1950s in Italy and the 1970s in Spain. In Latin America, however, the latifundium remains a dominant and even expanding form of productive organization that has profitably adjusted itself to the modern, dynamic, and export-oriented economy of late capitalism. With the exception of Mexico, Latin American agriculture is twice as large a sector as manufacturing, and three times as large as commerce. The greater part of the national wealth of many of these countries depends upon the production of coffee, sugar, bananas, cotton, and beef. The beef-producing latifundia, in particular, are expanding, benefiting from the international “hamburger connection.”

As Stanley Stein cautioned in 1961, we should not underestimate the political resilience of Latin America’s socioeconomic elites and their ability to adapt the latifundia system to late capitalism, using their influence to persuade sympathetic governments to provide infrastructure and protection. Although profitable, this system exacerbates the old latifundia/minifundia dichotomy, for Latin America’s agrarian structure is the most unequal in the world: ten of the fourteen countries with the highest concentration of land in the hands of single individuals are to be found there. This inequitable distribution lies at the root of the region’s persistent poverty. It was also the fundamental cause of civil wars and social uprisings in Guatemala, El Salvador, and Nicaragua during the 1980s and 1990s and more recently in Brazil and in the Mexican state of Chiapas.

LATINO NATIONAL POLITICAL SURVEY

The Latino National Political Survey (LNPS) of 1989–1990 is a nationally representative dataset designed to measure the political attitudes and behaviors of the three major Latino subgroups in the United States: Mexicans, Puerto Ricans, and Cubans. The principal investigators of the LNPS consisted of four political scientists—Rodolfo de la Garza, Angelo Falcon, F. Chris Garcia, and John A. Garcia. Temple University’s Institute for Survey Research conducted the survey.

DESCRIPTION OF THE LNPS

Data collection for the survey began in July 1989 and continued through March 1990. Latinos in the survey consist of individuals who reported having at least one parent or two grandparents (in any combination) of Mexican, Puerto Rican, or Cuban ancestry. The LNPS dataset includes 2,817 Latino respondents (1,546 Mexicans, 589 Puerto Ricans, and 682 Cubans).

The LNPS is the primary dataset examining the political attitudes and behaviors of Latinos on a national basis. According to the LNPS codebook, the survey contains a variety of variables, including the following broad categories: family history, organizational membership, political participation, voting behavior, attitudes toward a wide variety of political issues, attitudes toward a variety of racial/ethnic/national origin groups, and typical demographic characteristics (e.g., age, sex, and generational status). The dataset also includes information on the phenotype of respondents.

THE USES OF THE LNPS

The LNPS dataset has been disseminated widely. Indeed, it is available to researchers at the Inter-University Consortium for Political and Social Research (ICPSR).
Social science researchers, public policy practitioners, and the mass media have used the dataset.

The LNPS has been applied to a broad range of social science topics, including the political attitudes of Latinos, the correlation between discrimination and phenotypes, residential patterns among Latino groups, and migration/immigration issues facing Latino groups. For example, in 2002 the *Social Science Quarterly* published an article titled “Latino Phenotypic Discrimination Revisited: The Impact of Skin Color on Occupational Status” (Espinó and Franz 2002) based on the LNPS. This work showed that dark-skinned Mexicans and Cubans—but not Puerto Ricans—held less prestigious occupations than their lighter-skinned counterparts. In addition, *Social Science Quarterly* published another article in 2003 titled “The Corrosive Effect of Acculturation: How Mexican Americans Lose Political Trust” (Michelson 2003) using the LNPS. This particular article showed how political trust among Mexican Americans decreases with greater acculturation and exposure to mainstream society.

Social sciences such as economics and anthropology have also utilized the LNPS. For example, the journal *Applied Economics Letters* published an article in 2002 entitled “Passing on Blackness: Latinos, Race, and Earnings in the USA” (Darity, Hamilton, and Dietrich 2002). The article used previous findings from the LNPS to examine labor-market outcomes of people with Latino ancestry who also self-identify as black. Similarly, the anthropological journal *Transforming Anthropology* published an article in 2005 titled “Bleach in the Rainbow: Latin Ethnicity and Preference for Whiteness” (Darity, Dietrich, and Hamilton 2005). Like the economics-based study, this article examines Latinos, particularly Puerto Ricans, who self-identify as black. The article cited a previous study that examined racial self-characterization categories ranging between black and white.

The LNPS has also been used in recent years by public policy agencies to better understand the political attitudes and voting behaviors of Latinos. Groups such as the Pew Hispanic Center, a Washington, D.C., think tank, and the Center for Information and Research on Civic Learning and Encouragement have utilized the LNPS to better comprehend the political behaviors of this increasingly influential population group.

Furthermore, the national media have also used the LNPS. In the early 1990s the Associated Press (AP)—specifically *USA Today* (Benedetto 1991)—and *El Sol del Valle* (Contreras 1995) referenced the LNPS. Each of these news pieces discussed political and related attitudes and behaviors of Latinos. The AP’s usage of the LNPS demonstrates the wide application of this dataset.

**LIMITATIONS OF THE LNPS**

Despite the major contributions and the wide use of the LNPS, the dataset has some limitations. First, it focuses on only three Latino subgroups (Mexicans, Puerto Ricans, and Cubans). This creates a problem in generalizing the observed trends to other Latino groups such as Dominicans, Central Americans, and South Americans.

Second, as is typical of cross-sectional surveys, the information collected provides only a “snapshot” of individuals’ attitudes and behaviors at a single point in time (1989–1990). Thus, researchers using the LNPS cannot analyze temporal changes related to political attitudes and behaviors. Moreover, the data are now quite dated. Many important changes have taken place since 1990, especially with respect to the politics of immigration. Longitudinal datasets need to be developed in order to capture the major demographic, social, economic, and political changes taking place within the Latino population.

Third, while the LNPS has a major focus on the political attitudes and behaviors of Latinos, other important dimensions (immigration, education, health, work, and gender relations) of the Latino experience are neglected or receive little attention. A new dataset, funded by private and public agencies and research centers, will be available in the fall of 2007 through the University of Washington’s “WISER” Web site and the ICPSR. The new dataset, titled the Latino National Survey (LNS), focuses on the same ethnic groups as the LNPS (Mexicans, Cubans, and Puerto Ricans). This new survey is based on a random sample of 8,634 respondents interviewed by telephone. The sample is drawn from fifteen states and the District of Columbia. Selection of the states was based on Latino population estimates using U.S.
The civil rights movements of the 1950s and 1960s facilitated the implementation of Latino/a studies scholarship in U.S. colleges and universities. Activists fighting against systemic racism and discrimination provided an impetus for Latino/a students and faculty seeking scholarship that met the needs of Latinos/as in the United States. At the time Latinos/as were essentially invisible in mainstream white America. For instance, although both Chicano/as and Puerto Ricans represented the two largest Latino/a subgroups in the United States, their incorporation by conquest resulted in their limited participation and integration into political, social, and economic institutions.

The systemic exclusion and historical underrepresentation of people of color was reproduced in academic institutions of higher education. Scholars studying U.S. race relations regularly failed to take a critical view of the social, economic, and political disparities and realities of the Latino/a population. For example, scholars with research interests in the Mexican-origin population of the United States were “primarily concerned with understanding the reasons for the perceived inability of Mexicans to assimilate into American society in the manner of other ethnic groups, from Europe” (García, Lomelí, and Ortiz 1984, p. 1). Therefore Latino/a students and faculty sought to establish academic programs that rejected the colonizing ideology of white America, advocating instead the development of scholarship that provided students with critical knowledge and training of Latino/a culture and history (Rodríguez 1990; Muñoz 1984). The implementation of Latino/a studies programs concentrating on the issues affecting Latino/a communities and the development of resolutions that dealt with these were the goals of Latinos/as who were privileged to be affiliated with colleges and universities (Rodríguez 1990; Muñoz 1984).

With these issues in mind, Chicanos/as and Puerto Ricans paved the way for the development of Latino/a studies. Latino/a students and faculty pioneered changes at historically white colleges and universities, beginning with the creation of the first Chicano/a studies program at California State University, Los Angeles, in 1968 and following with Chicano/a studies programs at universities in the Southwest and Puerto Rican/Boricua studies programs in the Northeast. Despite these accomplishments, Latino/a studies programs have experienced a number of challenges. Marginalized within their respective institutions, programs have been underfunded, denied autonomy, and at times, subsumed within other programs in their respective colleges and universities (Caban 2003).

Influential in the creation of Latino/a studies scholarship were Latino/a student activists who protested and participated in strikes that confronted racial and class oppression (Muñoz 1984); Latino/a faculty also played...
pivotal roles in the creation of Latino/a studies programs. Julian Samora (1920–1996), the first Chicano to receive a doctorate degree in sociology and anthropology—in 1953 from Washington University in Saint Louis—was particularly important in establishing the field of Chicano/a studies. In addition to cofounding the National Council of La Raza and creating the Mexican American Legal Defense and Educational Fund, Samora mentored hundreds of undergraduate students and supervised the completion of more than fifty doctoral degrees at the Notre Dame University. His accomplishments influenced studies in the areas of bilingual education and immigration. In 1989 Michigan State University established a Latino/a research organization in his name, the Julian Samora Research Institute.

Likewise Frank Bonilla influenced the development of Puerto Rican/Boricua studies. Anne Quach chronicled Bonilla’s U.S. military experience, describing how it motivated his pursuit of an academic career (Quach 2004). His own interests, along with those of other young social activists, spurred the formation of the Puerto Rican Hispanic Leadership Forum, thus paving the way for the establishment of Aspira (Quach 2004). Aspira is the first national nonprofit organization to empower Latino/a youth through the development of leadership skills that motivate Latino/a community advancement. These organizations, which seek to meet the needs of Puerto Ricans and other Latinos/as, originated from a response to the racism and discrimination that Puerto Ricans faced in the United States. Bonilla’s interests also focused on issues of globalization and immigration (Quach 2004). Both Samora and Bonilla, along with many others, were pivotal forces in addressing the needs of Latinos/as in the United States, and they mentored many others toward initiating change.

In spite of their turbulent beginnings, Latino/a studies programs have gained academic legitimacy and produced scholarship directed toward multidisciplinary interests (Cabán 2003). Traditionally social science scholars in the disciplines of sociology and political science, for instance, focused Latino/a research in the areas of politics, sociology, political science, and economics. However, the emergence of interdisciplinarity research within the field has sprung from the very nature of the heterogeneity of the Latino/a origin population and resulted in a hybrid that acknowledges the diverse cultures and disciplinary interests of Latinos/as (Masud-Piloto 2003). By the 1990s Latino/a studies scholarship encompassed nontraditional areas of study, such as border studies, women’s studies, and performance and film studies (Masud-Piloto 2003). Further developments included the incarnation of “a multidisciplinary academic field that explores the diversity of localized and transnational experiences of Latin American and Caribbean national origin populations in the United States” (Cabán 2003, p. 6).

The origin of Latino/a studies scholarship was a response to the racial and class oppression faced by Chicanos/as and Puerto Ricans. Although programs face internal divisions and marginalization within their respective academic institutions, Latino/a studies programs continue to meet the needs of Latinos/as and to inspire students and faculty to examine various areas of research, thereby acknowledging the diversity of the Latino/a population.

LATINOS

The Latino population represents the largest minority group and most rapidly growing ethnic group in the United States. This population is composed of a variety of subgroups tracing their origins to Mexico, the Caribbean, Central America, South America, and Spain. While Latinos represented one-sixteenth of the U.S. population...
in 1980, they were one-seventh of the U.S. population in 2005, when they numbered 42.7 million. They accounted for two-fifths of the nearly 70 million people added to the national population between 1980 and 2005. Population projections indicate that Latinos will continue to drive the demographic changes in this country throughout the twenty-first century. Indeed, they are expected to make up 46 percent of all people projected to be added to the U.S. population between 2000 and 2030. Thus, by 2030 Latinos are predicted to number 73.1 million, accounting for one-fifth of all people in the nation.

This entry provides an overview of the emergence of the terminology to describe this population, the mode of incorporation of the major Latino populations into the United States, and the contemporary social and economic standing of the Latino population in the country.

THE IDENTIFICATION OF LATINOS
In the United States, race and ethnicity have been central to public discourse, government, and economics. Throughout U.S. history racial and ethnic categories functioned as a basis for inequality and discrimination. Governmental changes to identifiers during the twentieth century came as a result of the pursuit of civil and equal rights by minorities in areas regarding education, housing, employment, and public services. For instance, mid-twentieth-century civil unrest and subsequent legal challenges compelled the Federal Office of Management and Budget to develop the term Hispanic in 1970 to mean “a person of Mexican, Puerto Rican, Cuban, Central or South American or other Spanish culture or origin, regardless of race” (Hayes-Bautista and Chapa 1987, p. 64). While many adopted the Hispanic ethnic identity, many others eschewed the term as it failed to take into account the unique origins and historical experiences of distinct subgroups. Therefore, the term Latino has been widely adopted as a more acceptable term of self-identification by people of Latin American ancestry.

Despite pan-ethnic identifiers, the groups that make up the Latino population have diverse histories, cultures, and modes of incorporation into the United States. For instance, the initial incorporation of some groups occurred through warfare, while that of others was the result of civil unrest. For all groups, economics—the search for favorable employment—has been an attraction to the United States.

HISTORICAL OVERVIEW AND MODES OF INCORPORATION OF LATINO GROUPS
Over the course of 185 years, nearly 15 million people from Latin America migrated on a legal basis to the United States, according to the U.S. Department of Homeland Security in 2006. The majority of this movement took place during the late twentieth and early twenty-first centuries (77% of the 15 million immigrated after 1970). About 45 percent of all immigrants who entered the United States legally between 1970 and 2005 originated from Latin America. Mexico alone accounted for one-fifth of all legal immigrants entering the country during this period. The ten countries with the most Latinos immigrating to the United States from 2000 to 2005 were Mexico (867,417), El Salvador (139,390), Dominican Republic (127,066), Cuba (97,988), Colombia (91,808), Guatemala (78,594), Peru (58,318), Ecuador (47,094), Nicaragua (36,620), and Venezuela (32,500).

Latino groups have entered the United States at different periods under varying conditions. The two groups that have been in the United States the longest, Mexicans and Puerto Ricans, were initially incorporated into the United States through warfare. Numerous other groups—including Cubans, Guatemalans, Nicaraguans, and Salvadorans—have sought asylum in the United States due to warfare in their home countries. Still, the majority of Latin American immigrants came to the United States for economic reasons, drawn by labor opportunities and propelled by poor employment prospects in their home countries.

Mexicans Mexican, approximately three-fifths of all Latinos living in the United States, have been in the country the longest. Mexicans were incorporated through the Mexican-American War that Mexico lost, along with approximately half of its land, to the United States under the Treaty of Guadalupe Hidalgo of 1848. Mexicans who were living on what was now U.S. land were given the choice to remain and become U.S. citizens or return to Mexico. They overwhelmingly elected to remain on their land. Although Mexican Americans were guaranteed all rights as U.S. citizens, including respect for their property, culture, and language, as former Mexicans they became, at best, second-class citizens.

In actuality, Mexican Americans experienced colonization and exploitation as whites from other parts of the United States entered the acquired territories. Colonization included the loss of land due to legal and extralegal means, according to Rodolfo Acuña (2000) and David Montejano (1987). Mexican Americans became a landless proletariat and provided inexpensive labor for Anglo settlers. Similar to the situation that African Americans experienced in the South, Mexicans and Mexican Americans in the Southwest experienced great legal and illegal violence, discrimination, oppression, and disenfranchisement.
During the opening decades of the twentieth century, Mexicans fled political and civil unrest to the United States. Ironically, during a period when the United States was creating policies to keep southern and eastern Europeans and Asians from entering the country, many industrialists and growers welcomed Mexican immigrants as cheap labor for a growing economy. By the mid-1920s their growing presence, the country’s economic instability, and the xenophobic attitudes of whites compelled the U.S. government to evict Mexicans from the country. For example, approximately 500,000 Mexicans—roughly one-third of the Mexicans enumerated in the 1930 U.S. census—were repatriated to Mexico during the Great Depression. Within ten years the United States and the Mexican government colluded to establish the Bracero Program to deal with U.S. labor shortages associated with World War II; because of its wide popularity among U.S. employers, the Bracero Program was extended nearly two decades beyond the conclusion of the war. The program allowed United States employers to actively recruit and import Mexican contract labor to meet their needs. In all, approximately 4.7 million Mexicans came to the United States under this program. Since the 1970s, there has been a significant increase in Mexican immigrants and settlers. The entrance of U.S. capital into Mexico—in the form of the Border Industrialization Program and the North American Free Trade Agreement—have altered social and economic structures in Mexico that have helped to create the movement of workers (some of these displaced) to the United States. The combination of “old-timers” (those whose roots extend back multiple generations) and “newcomers” (those who have come to the United States in the recent past) has created a diverse Mexican-origin population, as described by Rogelio Saenz in his census report *Latinos and the Changing Face of America* (2004).

**Puerto Ricans** Puerto Ricans share a colonized past with Mexico. Indeed, the island of Puerto Rico has been marked by colonial exploitation beginning with its colonization by Spain and continuing into the present as a Commonwealth of the United States. The history of Puerto Rico is similar to that of other Latin American countries that have been under the sovereignty of colonial nation-states. The native people of the island were first colonized in 1493 by the Spanish. When this population declined as a result of forced labor and disease, according to the writers Joe R. Feagin and Claireece Booher Feagin in their book *Racial and Ethnic Relations* (1999), slaves were brought in to fill the labor gap until 1873, when slavery was abolished. Rule over Puerto Rico was ceded to the United States as result of the Spanish-American War and the subsequent signing of the Treaty of Paris in 1898. Puerto Ricans received U.S. citizenship with the passage of the Jones Act of 1917 and gained self-governance in 1952. However, although Puerto Ricans are U.S. citizens, island residents are not allowed to vote in U.S. presidential elections, but they are required to enlist in military service to the United States.

Puerto Rico functioned economically in an agricultural system until the late 1940s when a rapid program of industrialization, known as Operation Bootstrap, was introduced by then Governor Luis Munoz Marin. Operation Bootstrap allowed locally tax-exempt U.S. corporations to develop industries on the island, which placed an economic burden on the Puerto Ricans who were required to finance the necessary infrastructure through high personal taxes. Although Puerto Rican migration to the U.S. mainland existed prior to the rapid-industrialization projects, massive unemployment in the 1970s resulted in the migration of approximately one-third of the island’s population to the United States (Feagin and Feagin 1999).

Due to their U.S. citizenship status, Puerto Ricans tend to migrate in a circular pattern. Over the years many have settled in the United States. Puerto Ricans have subsequently had a major impact on mainstream American culture, especially in cities such as New York, where ethnic enclaves have existed since the 1920s.

**Cubans** The island of Cuba became a U.S. protectorate in early 1900, and in the middle of the twentieth century, through revolution, it became a socialist state. U.S. interest in Cuba arose out of economic investments by U.S. businesses. The United States became the major market for Cuban goods and a provider of essential supplies needed to sustain the island's economic system. The political instability on the island began in the 1930s and lasted through the 1950s; student-led protests, along with instability within the Cuban polity, threatened the economic, social, and political interests of capitalist Cuban elites, U.S. investors, and as a result the governments of both countries. Socioeconomic disparities led to the establishment of a socialist state with Fidel Castro in power beginning in 1959. Castro’s rise to power resulted in large-scale emigration of the middle and upper classes, who sought asylum in the United States. As advantaged political refugees fleeing what was labeled as a communist state by those who were adversely affected by Castro’s rise to power, Cuban refugees were offered numerous resettlement benefits by the United States.

Other refugees accepted into the United States in 1980, however, were not provided resettlement programs. This group, referred to as Marielitos (after the Cuban port from which they left, Mariel Bay), were drawn from the lower classes and were largely black. While the group included some criminals, the media exaggeratedly portrayed Marielitos as “undesirables,” write Alejandro Portes.
Latinos

Still, the favorable economic and human-resource assistance that the early waves of Cubans received helped some to achieve upward mobility in the United States. Cuban enclave enterprises have been highly successful in Miami and have helped integrate Cuban immigrants, according to Portes and Bach (1985).

Nicaraguans Significant immigration to the United States by Nicaraguans is often recognized as beginning in the late 1970s at the end of the regime of Anastasio Somoza Debayle. Immigrants were escaping a repressive government whose actions had impoverished the majority of the population, destabilized the economy, and started a U.S.-supported revolution. Nicaraguan immigration was characterized by three subsequent waves.

The initial arrivals were limited in number and composed of upper-class or elite families—industrialists, large landowners, and top businessmen—escaping the Sandinista takeover of the country. Many had the financial means and education required to establish themselves in the United States. Their arrival and presence was therefore much less noticeable than subsequent arrivals.

The second phase of Nicaraguan migration occurred in the early 1980s and consisted of political asylum–seeking urban, middle-class professionals and business personnel escaping a dysfunctional economy destabilized by political turmoil. Some used prior degrees and skills to find jobs, but the majority of immigrants were reduced to labor occupations until they could better accommodate themselves. State assistance was provided for them as long they had legal documentation. Improper documentation resulted in deportation procedures.

The third wave of immigrants began in the mid-1980s and consisted of laborers and peasants escaping the Contra war and a disrupted economy. Many resorted to the informal economy in order to earn subsistence wages. These arrivals initiated a recognizable flow that alarmed many Americans, who urged the U.S. government to respond.

Unlike the Cuban experience, but much like that of other Central and South Americans, Nicaraguans were hardly welcomed to the United States or given much opportunity for permanent settlement. By the late 1980s, the Reagan administration’s support for the Contra military was overtly stopped, and the flood of refugees to the United States seeking asylum increased exponentially. In an effort to stop the flow of refugees, the United States detained and incarcerated all new arrivals while their cases for asylum were processed. The U.S. Immigration and Naturalization Services classified most as illegal aliens and initiated deportation. Established Nicaraguans attempted to intercede, but U.S.-supported political changes in Nicaragua compelled democratic changes and prompted refugees to return. In contrast to other refugee groups, Nicaraguans were offered no resettlement programs, note Portes and Alex Stepick in City on the Edge: The Transformation of Miami (1993).

CONTEMPORARY AMERICA

Latinos have comparable, yet distinct immigration experiences. Foreign policies and territorial ambitions coupled with the United States’ need for cheap labor established the initial ties between Latin America and the United States, paving the way for immigration and setting the stage for Latino identity in the United States, as described by José Calderón in his contribution to Latin American Perspectives (1992). Latino Americans who settled in the United States are represented in all socioeconomic classes and at various stages of assimilation or acculturation. Latino subgroups have established distinct communities around the country. Ethnic enclaves attract newcomers that reinvigorate immigrant culture, and each successive generation blends with mainstream American culture, shaping a new identity for Latinos.

There is a significant amount of stratification within the Latino population, notes Saenz (2004). Cubans and South Americans tend to have the highest levels of socioeconomic achievement in the United States, while Mexicans, Puerto Ricans, Dominicans, and, to some extent, Central Americans are positioned at the bottom of the socioeconomic ladder.

Nonetheless, due to their increasing numbers, Latinos have begun to achieve some degree of political success. Furthermore, because they are situated in urban areas and in the most populous states, they are a group that politicians must acknowledge. However, other forces tend to limit the political power of Latinos: They are a young population (with many not old enough to vote), many Latinos cannot vote because they are not U.S. citizens, and they are noticeably divided across national origin and class lines.

The presence of a diverse and growing Latino population may diminish Anglo cultural dominance and introduce a sense of multiculturalism to U.S. society. As Latinos retain and assert their own ethnic identities, they add cultural distinction to their respective geographical centers across the United States.

As a consumer group, Latinos have been recognized by marketing agencies and corporations who previously had failed to target this large group and their buying
potential, observes Arlene Dávila in *Latinos, Inc.: The Marketing and Making of a People* (2001). In this regard, the influence of Latinos in the labor market and their presence as a consumer force impact economics in the United States and abroad.

**LAUSANNE, SCHOOL OF**

The expression “School of Lausanne” indicates the body of ideas and analytical techniques associated with the early mathematical formulations of general economic equilibrium, due to Léon Walras (1834–1910) and Vilfredo Pareto (1848–1923); later writers working in that field are occasionally classified as belonging to the School of Lausanne as well.

In 1870, the Frenchman Léon Walras was appointed to the newly created chair of political economy at the University of Lausanne, Switzerland. Walras aimed at attacking *La Question Sociale* (the problem of the distribution of social wealth) by means of a new approach to economics and social economics revolutionizing its philosophical foundations. He aimed at discovering the scientific laws of the most equitable distribution of the most abundant production. Walras pursued this project during his entire life, but he only managed to achieve a systematic presentation of his Pure economics (Éléments d’économie politique pure, 1874–1877, 1889, 1896, 1900). As Walras surrendered to age and fragile health, in the end his theory of distribution of social wealth (social economics) and his theory of production of social wealth (applied economics) had to appear as collections of articles under...
the titles Études d'économie sociale (1896) and Études d'économie politique appliquée (1898).

In 1893 the Italian Vilfredo Pareto succeeded Walras, taking over the chair officially on October 23, 1894. While retaining Walras's general equilibrium approach, Pareto severed it from social economics and renounced its use as a conceptual tool to deal with La Question Sociale, thereby denying that it can serve any purpose as an instrument for social reform. In fact, Pareto came from a quite different ideological tradition and was much more concerned with the demonstration of the advantages of free trade than with La Question Sociale. Their philosophical backgrounds are not quite the same either. Walras was an heir to the tradition of French rationalism whereas Pareto was influenced by the English empiricists. In fact, notwithstanding the rather similar mathematical models, Walras and Pareto strongly disagreed regarding to what extent equilibrium is supposed to refer. The relationship of individual choices and the market was also interpreted in radically different ways. Whereas for Walras free and absolute competition is a pure, idealized mechanism that logically comes before the actual individual actions, Pareto takes the individual actions as his starting point and sets them in the context of perfect competition as a market form. There are hints of this change of approach beginning with Pareto's Cours d'Économie politique professé à l'Université de Lausanne (1896–1897). However, it was in the Manuale di Economia politica con una introduzione alla scienza sociale (Manual of political economy, with an introduction to social science, 1906) that Pareto set out the foundation of the modern theory of rational choice, characterized by an ordinal ordering of preferences.

This was perhaps the last important contribution of the Lausanne School to economic theory. Later, in fact, Pareto turned away from the study of individual logical action (pertaining to economics) and dedicated himself to the study of non-logical actions (the domain of sociology). The few articles written by Pasquale Boninsegni (1869–1939), who succeeded Pareto at Lausanne and taught at the University until 1939, did not supply theoretical advances comparable to his predecessors’ achievements.

The School of Lausanne is important not only for its theoretical contributions, but also for its attempt to couch them in mathematical form, or at any rate for having interpreted economic mechanisms by means of mathematical procedures. Walras and Pareto paved the way for the mathematization of economics, and accordingly the School is often referred to as the Mathematical school.

This feature attracted the attention of some renowned mathematicians, beginning with those participating in Karl Menger's Vienna seminar in the 1930s and later with some at the Cowles Commission for Research in Economics in Chicago.

These new contributors shifted the focus of research toward the formal aspects of the general equilibrium approach, in particular the issues of existence, uniqueness, and stability of equilibrium, leaving the heuristic aspects aside. The existence and uniqueness of a general equilibrium solution were established in the 1950s. The issue of its stability, however, has not yet been solved, and there are indications that it will remain unsettled. In other words, one can prove that under some carefully chosen assumptions in a perfectly competitive world individual choices are mutually compatible; but it is highly unlikely that such coordination actually takes place.

LAW

The importance of law is much more easily determined than its definition. Law is perhaps the most conspicuous arena wherein theory and practice meet. Law often acts as a catalyst in society, introducing ideas and solutions that might not otherwise take hold. Law can also act as a barrier to social progress and justice. The civil rights legislation of the 1960s, constructed in part to end desegregation in the U.S. South, is an example of law as a catalyst. The very laws overturned by the civil rights legislation illustrate how law can impede social change. Law also reacts to cultural and moral developments and can be understood as responding to a new social consensus or understanding. In this sense the same civil rights legislation that acted as a catalyst in one region of the United States can be said to have simultaneously reflected a growing national consensus; in this case, a national judgment that racial segregation in public schools was a gross violation of American ideals.

But if law, and the study of law, is important because of its obvious connection to social problems and social
change, what exactly is it? For a straightforward definition one need only consult Black's Law Dictionary, which describes law as a “rule of civil conduct prescribed by the supreme power in a state,” or more fully, a law is a “general rule of human action, taking cognizance only of external acts, enforced by a determinate authority, which authority is human, and among human authorities is that which is paramount in a political society.”

These definitions are helpful in identifying some important features of the law and legal systems. Not surprisingly, however, such definitions cannot entirely capture other salient features of what is meant by the term law. A more comprehensive approach to the question of what law is involves taking a closer look at some of the most important components of law. Finally, some of the different types of law must be examined, as well as methods of approaching the study of law.

ELEMENTS OF THE LAW

In what remains one of the most elegant and insightful investigations into the nature of law, the English scholar H. L. A. Hart opens his 1961 book The Concept of Law by noting that law is a unique discipline. Chemists, professors of French literature, and medical doctors do not expend a great deal of intellectual energy on the question of what comprises chemistry, French literature, or medicine. Yet scholars who study law, also known in this context as jurisprudence or philosophy of law, have created a voluminous literature dedicated to the question of the essence of law.

This seems rather odd, given that most of us would have no problem identifying examples of “the law.” Hart describes five features that we would expect to find in a legal system ([1961] 1994, p. 3). First, there are laws mandating some actions (e.g., wearing a seatbelt in a car) while prohibiting others (e.g., driving the car above a certain speed limit). If citizens run afoul of such laws, and are convicted as such, there are prescribed punishments. Second, there are rules that require citizens to repay those whom they have injured in some way. Third, there are laws that allow citizens to create legally recognized relationships that did not exist before; for example, marriage and contract laws. Fourth, there are courts created by law for the express purpose of determining when and how laws have been broken and what recompense is warranted. Finally, there is a special category of law that concerns how new laws are created. Article 1 of the U.S. Constitution is an example of this sort of law, as it specifies how Congress as the legislative branch can create new law.

But note that these bare minimum characteristics describe a legal system, not necessarily the law itself. How might one understand the difference? Although there is some conceptual overlap between the two terms and they are often used interchangeably, generally, legal systems are concrete attempts to instantiate laws within a given political community. Some examples include the U.S. legal system, the British legal system, and the Chinese legal system. Social scientists can describe various legal systems with more precision than they can the more ambiguous concept of law itself. A legal system can be explained by reference to its constitution, legal traditions, and the actual practices of a government; a flow chart can show the defining governing bodies, powers, checks, and legal rights and responsibilities. However, defining and understanding various legal systems does not do away with the need to understand law as conceptually distinct from the various legal systems that attempt to instantiate and embody different understandings of law. One need only consider, as Hart notes, that the very constitutional conventions that establish modern legal systems have something to do with law, yet cannot themselves be understood as identical with the legal systems they create. Legal systems, however they may differ from nation to nation, are attempts to instantiate law.

What, then, is the purpose of law? Law exists to secure social and public goods, which include such important political priorities as order, justice, equality, and liberty. In short, and paraphrasing legal scholar Ronald Dworkin’s introduction to his influential 1986 tome Law’s Empire, we “live in and by the law,” pursuing our goals and relationships, our identities and our livelihoods, within the framework created and maintained by a system of laws.

But this does not capture all the essential elements of what law is or how law works in society. A system of law has by definition at least an element of coercion. Laws that prescribe or enjoin behaviors have attached to them penalties that must be enforced by some level of government. As Hart’s example of a marriage law illustrates, not every law has a punitive or coercive element to it, but given the impossibility of voluntary and unanimous adherence to laws, coercion and punishment are necessary components of a legal system.

This notion of coercion leads naturally to the questions of authority and legitimacy and their relation to a society’s laws. By what authority are laws made, and who has the right to enforce them? One answer to this question is based purely on power. Whoever can impose laws and enforce them has authority. But this answer collapses any understanding of what is lawful into a mere description of who holds power. It undercuts a basic intuition that law serves a normative purpose and can be imposed by a legitimate governing body. Most liberal constitutional democracies, at a procedural minimum, understand a legitimate governing body to be one that enjoys the consent of those governed by its laws and is ultimately accountable for its representation of its citizens through fair and regular elections.
Legitimacy itself is best understood as a normative or moral concept, and it highlights the link between law and morality. Scholars differ as to exactly how morality and law are related, and as to how morality should inform descriptions and theorizing about law, but there is some general agreement that describing law accurately entails some measure of understanding of what actors in the legal arena aim to do. Thus one is brought back to the social goals mentioned previously: justice, order, freedom, and the like. These are inherently normative concepts, the realization of which can be understood as making society somehow better. Traffic laws, for example, aim at providing an orderly and safe means of transportation. This in turn protects the value one's society places on life, commerce, free movement, and so on. To be sure, there are often tensions between social goods, such as liberty and security, and laws are often inefficient means of promoting or securing such goods (indeed, laws themselves can be instruments of injustice). Moreover, the content of morality and law are not identical. Many citizens might consider a given behavior, for example gossiping, to be immoral without thinking that it should also be illegal. Nevertheless, there does seem to be a connection between law, its social function, and morality. It is difficult to persuasively describe what law is without making at least some reference to a society's understanding of what law ought to be.

**TYPES OF LAW**

Legal emphases and specialties have proliferated to the point where categorizing all the different types of law is a Herculean task. In addition to traditional subject areas such as contract law, torts, criminal law, and constitutional law, prospective lawyers, social scientists, and interested laypersons can expect to find new avenues of research and study in environmental law, election law, intellectual property law, Internet law, and law pertaining to the rights of indigenous peoples, to name just a few. With that in mind, a few words are in order about some of the central areas of law: constitutional law, criminal law, and torts.

**Constitutional Law** A constitution acts as the framing document of a given political entity. Often, constitutions will include an aspirational preamble, a declaration or bill of rights, explicit means whereby the constitution may be amended, and the basic framework of the government's bodies in their executive, legislative, or judicial functions. Constitutions vary a great deal, not only in their allotment of political responsibility but also in their means of interpretation. In the British parliamentary system the executive and legislative functions are both found in Parliament, whereas the U.S. Constitution places legislative duties with Congress and executive duties with the president. In some European nations a court must review the constitutionality of every piece of legislation; in the United States the Supreme Court does not review the constitutionality of a law unless a citizen or state pursues the issue through the lower courts.

Constitutional law, then, is the practice of law that concerns itself both with applying constitutional norms to contemporary issues and with arguments about the constitution itself. An example of the former is found in deciding how to apply constitutional provisions to new technologies or developments. For example, the framers of the U.S. Constitution forbade “unreasonable search and seizure” but could not have anticipated how to apply this norm to telephone technology and wiretapping. Constitutional law is also the purview of those who might want to change the constitution itself.

**Criminal Law** One of the major areas addressed by constitutional law is criminal law. Criminal law addresses wrongs that are public in nature. District attorneys prosecute crimes in the name of the people of their particular state, province, or city. This is because some wrongs are seen as injuring not only the individual victim, but also the wider public. Criminal law includes prohibited and required actions as well as the safeguards in place to ensure fair trials and sentencing. Obviously this area is most closely identified with the coercive element of law.

**Torts** Not all wrongs committed between citizens are considered public wrongs that would be tried in a criminal court. These other wrongs are called torts, or civil wrongs, and these sorts of cases are what is commonly meant when lawsuits are filed between citizens. One of the chief differences between civil and criminal trials is that in a civil trial the state acts as a facilitator in the attempt to resolve the conflict, whereas in a criminal trial the state, in its executive function, is itself a party in the dispute. Another key difference is that damages in a civil trial are usually monetary; in a criminal trial prison time in addition to monetary fines is a frequent punishment. Occasionally the same event can result in both a criminal and civil trial. One famous example of this is the 1994 murder of Ron Goldman and Nicole Brown Simpson. O. J. Simpson was found not guilty in the criminal case brought against him by the state of California in 1995, but the parents of Ron Goldman sued successfully for damages in civil court in 1997.

**TWO METHODOLOGICAL AIDS**

The topic of law can certainly seem overwhelming given the innumerable manifestations of law, debates over its essence and application, and differing social science approaches in how to describe law and its relation to pol-
itics and society. There are two methodological aids that may be helpful for anyone interested in pursuing the study of law regardless of discipline (i.e., law school, sociology of law, philosophy of law).

The Central Case The “central case” method is useful for trying to determine what counts as law or a legal system, given that such descriptions are not always a clear matter of either-or categorization. For example, international law courts have many of the salient features of a legal system save one, coercion. There is as yet no authority superior to a nation-state to enforce international law. If coercion is a necessary feature of a legal system, should international law be categorized as law, or something else? The legal philosopher John Finnis in his 1981 book Natural Law and Natural Rights builds on insights from the ancient Greek philosopher Aristotle and contemporary legal philosopher Joseph Raz in presenting the central case as a useful tool (pp. 9–16).

What the central case method allows one to do is articulate several key elements of a legal system and thus identify an authoritative definition of law without having to then dismiss every example that does not exhibit every single key element, or does not exhibit them to the same degree. For example, one might describe the central case of constitutional government as being one that includes the rule of law, regular and fair elections, separation of powers, and an independent judiciary. A political scientist working on comparative legal systems can identify nations whose legal systems fulfill these criteria, as well as nations that are missing one of these elements (e.g., an independent judiciary). We might describe such a nation’s legal system as being a somewhat watered-down version of the central case. The central case method is a useful tool that allows observers to describe legal and social phenomena with enough flexibility to allow for real-world conditions that are not always amenable to orderly categorizations.

The Internal Point of View Another of H. L. A. Hart’s contributions to the study of law is the internal point of view (Hart [1961] 1994, pp. 89–91). The social scientist or observer who utilizes the internal point of view counts as worthwhile knowledge the self-understanding of the actors in any given system or social group. Consider for example U.S. Supreme Court Justice Oliver Wendell Holmes’s famous definition of law in his 1897 “The Path of the Law” address, that law is the “prophecies of what the courts will do in fact” (1920, p. 173). Whatever merit this view of law might have, it does not take into account what judges and lawmakers understand themselves to be doing. Legislators who pass laws, and judges who interpret them, understand themselves to be doing more than merely guessing how judges will rule on various situations in the future. Hart’s point is not that one need adopt the viewpoint of the judge, or anyone else, as one’s own. Rather, his argument is that one cannot accurately describe social phenomena without taking the internal view into account, precisely because those internal views are themselves part of the social phenomena and they help explain actions taken by legal actors in the system.

When faced with any study or explanation of legal behavior or phenomena, the notion of the internal point of view is helpful. Does a particular study of why judges decide cases the way they do take into account how judges understand their own role? If not, do the authors offer a persuasive explanation for their methodological choices? If nothing else, understanding Hart’s endorsement of taking into account the internal point of view encourages the student of law and legal phenomena to be aware of important questions regarding the objectivity and accuracy of legal theorists and social scientists.

LAW, JOHN
1671–1729

John Law was an outstanding monetary theorist who, unusually for a theorist, was given the opportunity to implement his monetary theory as policy. This he did during the 1716–1720 period through the Indies Company (Compagnie des Indes), which was popularly known as the Mississippi Company. The shares of this company rose from a low of 150 livres in 1717 to a high of over 10,000 in early January 1720, producing in the process Europe’s first major stock-market boom. Such was the success of Law’s policy in its initial phases that he was made controller-general of finances, a position akin to prime minister of France, at the start of 1720. Fearing that Law’s success with the Mississippi Company was regenerating the French economy, the British government authorized the South Sea Company to carry out similar debt-management style operations in 1720, resulting in a considerable boom in share prices in London up to August 1720. The subsequent collapses of both the Mississippi and the South Sea companies in the autumn of 1720 had considerable repercussions in delaying the development of the financial systems of France and, to a lesser extent, Great Britain until well into the nineteenth century. As a result of the failure of his company, Law was exorciated by contemporaries and later by a long line of distinguished economists including Richard Cantillon (1680–1734), Adam Smith (1723–1790), Karl Marx (1818–1883), and Alfred Marshall (1842–1924).

These criticisms were unfair to Law in that he was a man with thoroughly modern conceptions of money and banking. Law had the advantage that he was born the son of an Edinburgh goldsmith in 1671 at a time when goldsmiths were becoming embryonic bankers. His early career did not result in him following this banking gene. Instead, Law became a rake, a gambler, and a philanderer in London in the early 1690s. He killed a rival, Edmund Wilson, in a duel in Bloomsbury in 1694. Arrested for killing Wilson, Law was sentenced to death. However, he escaped from the gallows, most probably assisted by high-ranking members of the government. Law was forced to travel to the Continent. There, using his mathematical knowledge, he made a fortune at the gambling tables. He also became highly interested in the banking systems that he observed in Italy and Holland. Law’s new interest in banking encouraged him to send proposals to the English and Scottish authorities in 1704 and 1705.

Law outlined his monetary theory in two major works: John Law’s Essay on a Land Bank, written around 1704 but not published until 1994, and Money and Trade Considered (1705). In the former work, Law became the first economist to introduce the term demand in its proper economic sense into English. He then introduced the concept of the demand for money, and showed how inflation could arise when the demand for money was out of line with the supply of money. These were extraordinary achievements for someone writing in the first decade of the eighteenth century. In Money and Trade, he attempted to show the real role of money in the economy, contending that an increase in the money supply would generate increases in economic activity when there were unutilized resources in the economy, as was the case in Scotland in 1705. Law presented a rudimentary, circular flow-of-income model of the economy, the money-in-advance requirement, and the law of one price.

Law was provided with the opportunity to implement his monetary theories in France after the death of Louis XIV in 1715. In 1716 Law created the General Bank, and followed this a year later with the establishment of the Company of the West, which became the Mississippi Company. The General Bank, later transformed into the Royal Bank, attempted to solve France’s monetary crisis through the issue of banknotes, while the Mississippi Company addressed the problems of debt management and the development of colonial trade, particularly that of North America, where the Mississippi Company claimed ownership of all the lands between the British holdings in the Carolinas and those of the Spanish in Texas. In theory, this meant that the company had claims to half of the current contiguous United States. Law hoped that by swapping the equity of the Mississippi Company for government debt, he could greatly reduce France’s debt problem. Initially, the system worked, and people flocked to Paris to invest in the company. However, Law had created a financial circuit that was out of line with the real economy. When he attempted to address this problem in May 1720 by reducing the value of shares and paper money, confidence in the system was lost, and by December 1720 he was forced to flee from France. He was nearly brought back to France in 1723, at the invitation of the regent, Philippe (1674–1723), duke of Orléans. However, the latter’s sudden death stopped that possibility. Law died in Venice in 1729.

Law believed that money was the value by which goods are exchanged and not the value for which goods are exchanged. This placed him on the outside of most economic theory of his time, because he was asserting that money did not need to be intrinsically valuable. He wanted to rid the monetary system of the use of gold and silver, and replace these metals with paper money and bank credit. For a short period in France, he showed that this was possible, but it would take another 250 years before the final link with the gold standard was broken by the decision of the United States to refuse to guarantee the price of the dollar in terms of gold.

LAW AND ECONOMICS

Since the 1970s, a new approach to the analysis of law has developed. Known as law and economics, its focus is on identifying the effects of legal rules. Law and economics addresses questions like these: What is the effect on the number of automobile accidents of legal rules that hold negligent drivers responsible for harms that they cause? What is the influence on the amount of pollution of laws that penalize firms for releasing harmful wastes into the environment? Does the death penalty reduce the number of murders, and if so, by how much? In seeking to answer such questions, economic analysts generally assume that individuals and firms want to avoid legal sanctions, and the analysts often use data and statistics to verify their theoretical predictions.

Despite its name, the law and economics approach is not necessarily concerned with matters of money or markets. Determining the effects of the death penalty, for example, involves, among other things, consideration of whether an incensed individual would be deterred from shooting someone by fear of the punishment of execution.

The economic aspect of law and economics lies in its emphasis on incentives in predicting behavior. In the field of economics proper, the incentives are to make profits or to find a good price; here the incentives are to avoid legal sanctions.

Because economic analysis of law allows the effects of legal rules to be ascertained, the approach is useful for evaluating and comparing rules with regard to their social desirability. If, for example, it is found that the death penalty fails to deter murders carried out by incensed individuals, then it might be concluded that the death penalty is undesirable as a punishment for such murders.

Economic analysis of law has been controversial, mainly because it is centered on identifying the effects of legal rules rather than on the fairness of the rules, the focal issue of traditional analysis. The economic approach to law can be traced in significant respects to the English philosopher Jeremy Bentham (1789), and its modern pioneers include Ronald Coase (1960), Guido Calabresi (1970), and Richard Posner (1972). Posner is also an exponent of the hypothesis that the legal rules that exist are approximately rational in the sense that the consequences of their use are socially desirable.

This entry will provide two illustrations of the economic approach to the analysis of law and will make comparisons with traditional analysis of law. The first illustration concerns legal liability for harm caused in accidents, such as automobile accidents, oil spills, and construction mishaps like the collapse of a crane. A major effect of legal liability is that it fosters the taking of precautions. For instance, in order to avoid being held liable for harm due to an oil spill, the owner of a supertanker might install better navigation devices or hire more experienced crews. Or consider a numerical example: Suppose that if a person does not take a precaution, it is certain that his activity will cause harm of $100,000, for which he would be held liable. If he takes the precaution, however, he would definitely prevent the harm. The precaution would cost $30,000. Then the person would be induced to spend the $30,000 because it would save him a liability expense of $100,000. Such logic underlies the conclusion that, under many forms of liability, parties will be led to take socially desirable risk-reducing steps, and empirical evidence suggests that the liability system has often substantially reduced harm from accidents.

A number of complications arise in assessing how the threat of liability for accidents affects behavior. One issue involves liability insurance, which covers insured parties if they are held liable for harm. If the owner of a supertanker has liability insurance protecting it against having to pay for harm caused by an oil spill, the owner’s reason to invest in navigation devices to prevent spills might be dulled. However, the liability insurer might insist that the...
owner install such devices. Another complication is that parties who cause harm might themselves suffer harm in accidents, as is true in automobile accidents. In this situation, parties have a strong reason to avoid causing accidents, regardless of the threat of being held liable. Taking such factors into account is necessary to obtain good estimates of the influence of liability on accidents.

Given analysis of the effects of liability in reducing accidents, questions about legal policy can be addressed. For example, would raising the amount that has to be paid for oil spills significantly reduce the number of oil spills? A radical question is whether, in some areas of activity, it is worthwhile using the liability system at all. This question is an important one in view of the high costs of the liability system. It is estimated that for every dollar that an accident victim receives through the liability system, approximately one additional dollar is spent on lawyers, making the liability system extremely expensive for society to employ. For that reason, economic analysis suggests that, unless the liability system substantially reduces the number of some type of accident, the system may not be worthwhile for that type of accident. Consider automobile accidents. Liability may not much reduce the number of automobile accidents, since the fear of being injured in an accident (or of being arrested for drunk driving) may already provide most drivers with a sufficient motive to drive with reasonable care. Hence, it might be advantageous for society to do away with the liability system for automobile accidents (something that has largely been done in a number of American states).

The foregoing economic analysis of legal liability for accidents may be contrasted with traditional legal analysis of the topic. Traditional analysis stresses the perceived fairness of liability, and notably, the view that an individual who wrongfully injures another ought to compensate the victim for his losses. Under traditional analysis, liability is often seen as desirable without real regard to the degree to which it reduces the number of accidents or the costs of its use (or to the ability of accident victims to obtain compensation through their insurance policies). At the same time, economic analysts have generally not considered notions of the fairness of liability, although this issue is now beginning to receive some attention from them.

The second illustration of the economic approach to the analysis of law relates to a specific legal doctrine. When a person is making a contract, the law may impose on the person an obligation to disclose material information to the other party to the contract. For example, if a person is selling a home with a leaky basement, the person might be required to disclose this fact to the buyer. Or if an oil company is purchasing land and believes oil is likely to be found there, the company might have a duty to disclose this information to the seller.

Under the economic approach to law, emphasis is given to ascertaining the effects of a disclosure obligation. In the case of leaky basements, a principal effect of a disclosure obligation is that buyers will know about problems and will be able to take appropriate remedial steps, such as not storing valuables in the basement. Hence, a disclosure obligation for such problems as leaky basements may be socially desirable. However, the case of oil and land is different. If oil companies must reveal their knowledge about the high oil-bearing potential of land, they will have to pay significantly higher amounts to purchase land with promising potential. This will tend to reduce the willingness of oil companies to make investments, such as in geological surveys, to locate land with good oil-bearing potential. (Note that this issue of acquisition of information is not relevant in the case of leaky basements—homeowners will automatically learn about leaks, just because they live in their homes.) Therefore, it might not be desirable to obligate buyers to disclose what they know in situations like that of an oil company purchasing land (and, in fact, the law sometimes does not impose an obligation to disclose in these situations).

Under traditional analysis of law, the consideration of a disclosure obligation has mainly to do with whether it would be seen as unfair or immoral not to disclose information at the time of contracting. From this perspective, it might be thought that both a homeowner with knowledge of a leaky basement and an oil company with knowledge that there is probably valuable oil under a person’s land ought to reveal their information, for it would be underhanded, and perhaps akin to a lie, not to do so. Under traditional analysis, there would be no obvious reason to draw a distinction between the two types of cases, and the effects of the disclosure obligation on behavior and outcomes would not be the focus of attention.

These two illustrations show the importance of economic analysis of law, that is, of identifying the effects of legal rules, and the contrast between economic analysis and traditional analysis of law. Over time, economic analysis of law is likely to have a major, if not a revolutionary, influence on the understanding of law and on law-making activity.

LAW AND ORDER
The term law and order refers to a prominent theme of Richard Nixon’s (1913–1994) successful 1968 campaign for the American presidency. Law and order became a potent campaign symbol for Nixon, and related themes have sometimes surfaced in later Republican presidential campaigns—especially in 1972 and 1988. The term law and order is a political symbol capturing public anxieties about civil unrest, urban riots, black militant groups (which, some charged, fomented violence), and rising crime rates. Later events, such as the violence in the Boston area in response to court-ordered busing, widely publicized crime sprees like the Son of Sam murders in New York City, and continued rising crime rates, stoked fears of societal breakdown during the 1970s and gave law-and-order appeals additional resonance. These developments, sometimes connected with subtle racial appeals, contributed to the erosion of the Democratic Party’s dominant position in American politics after 1968.

1962 TO 1965: VIOLENT RESISTANCE TO CIVIL RIGHTS
After a period of relative domestic tranquility in the 1950s, the 1960s came as a rude shock to many Americans. Between 1961 and 1964, violent actions by southern whites bent on defending racial segregation became commonplace. Demonstrators at sit-ins and freedom rides, black and white, faced actual or threatened violence and mass arrests on fabricated charges. More violence erupted as federal officials attempted to carry out court-ordered desegregation. When black student James Meredith sought to enroll at (and integrate) the University of Mississippi, thousands of segregationists rioted, resulting in two deaths and forcing President John F. Kennedy (1917–1963) to mobilize thousands of troops to restore order.

As the civil rights movement continued, it was met with more violence. Police in Birmingham, Alabama, deployed dogs and high-pressure water cannons against unarmed civil rights demonstrators in 1963. The murders of National Association for the Advancement of Colored People (NAACP) leader Medgar Evers in Jackson, Mississippi, in 1963 and of three civil rights workers near Philadelphia, Mississippi, in 1964 fed fears of mounting social unrest. A 1963 bombing of a Birmingham black church killed four little girls, and Alabama state troopers attacked unarmed voting-rights marchers with dogs and electric cattle prods in March 1965. These cumulative shocks to the national consciousness were amplified by the 1963 assassination of President Kennedy in Dallas, Texas.

1965 TO 1970: BLACK MILITANT GROUPS AND URBAN UNREST
In response to white violence against civil rights activists, some black leaders adopted increasingly belligerent rhetoric. The rise of black radicalism was personified in militants like Stokely Carmichael (1941–1998) and H. Rap Brown. As political scientists Donald Kinder and Lynn Sanders noted, the new rhetoric frightened many whites. There was “less talk of nonviolence and more of self-defense; less yearning for integration and more for solidarity and black nationalism; ‘We Shall Overcome’ was replaced by Black Power and ‘burn, baby, burn’ ” (1996, p. 103). The image of neatly-dressed blacks pummeled by vicious white violence faded, replaced by images of blacks rampaging through city streets, torching cars and buildings and looting stores. The initial trigger for the changing imagery was the August 1965 Watts riot in Los Angeles. As Kinder and Sanders described the Watts riot:

The violence raged unchecked for three days, and three days longer in sporadic eruptions. Blacks looted stores, set fires, burned cars, and shot at policemen and firemen. Before the violence was halted, 14,000 National Guard troops, 1,000 policemen and 700 sheriff’s deputies were deployed to service…. In the end, 1,000 buildings were damaged, burned, looted or completely destroyed; almost 4,000 people were arrested; more than 1,000 were injured seriously enough to require medical treatment; and 34 were dead, all but three of them black. (Kinder and Sanders 1996, p. 103)

Watts was only the beginning, as 1966, 1967, and 1968 each brought more unrest. In 1967, 250 serious uprisings occurred, including the Detroit riots, which killed forty-three people. More disturbances erupted in multiple cities after the assassination of Martin Luther King Jr. in April 1968. As Kinder and Sanders observe:

For one long, hot summer after another, Americans watched what appeared to be the coming apart of their own country. On the front page of their morning newspapers and on their television screens in the evening appeared dramatic and frightening pictures of devastation and ruin: cities on fire, mobs of blacks looting stores and hurling rocks at police, tanks rumbling down the avenues of American cities…. Discussion of the “race
problem” in America … centered on the threat that inner-city blacks posed to social order and public safety. (Kinder and Sanders 1996, p. 103)

In 1968 the Kerner Commission released a report on the civil disturbances, warning that the United States was “moving toward two societies, one black, one white—separate and unequal.” The urban violence and Kerner Commission report created an opening for Republicans to pounce on the law-and-order theme. Republican presidential candidate Richard Nixon blasted the report for “blaming everybody for the riots except the perpetrators of violence,” promising “retaliation against the perpetrators” that would be “swift and sure.” As noted by journalists Thomas Edsall and Mary Edsall, Nixon’s running mate, hard-line Maryland governor Spiro Agnew (1918–1996), summoned black leaders in Baltimore to a stormy meeting where he accused them of cowardice for refusing to renounce black militant leaders like Stokely Carmichael and H. Rap Brown. Speaking of the violence in Baltimore after the King assassination, Agnew charged: “The looting and rioting which has engulfed our city during the past several days did not occur by chance. It is no mere coincidence that a national disciple of violence, Mr. Stokely Carmichael, was observed meeting with local black power advocates and known criminals in Baltimore three days before the riots began” (quoted in Edsall and Edsall 1991, p. 85).

The 1968 Democratic national convention met in Chicago following the June 1968 assassination of Democratic presidential candidate Robert Kennedy. Chaotic scenes of police beating demonstrators in Chicago’s streets and parks echoed the tumult within the convention hall, as party delegates splintered over the Vietnam War (1957–1975). By 1965 almost all American homes had televisions, bringing searing images of one dramatic (and sometimes horrifying) event after another into the public consciousness. The racial subtext to much of the unrest of the 1960s is unmistakable. As Kinder and Sanders note:

The riots opened up a huge racial rift. Fear and revulsion against the violence were widespread among both white and black Americans, but whites were much more likely to condemn those who participated in the riots and more eager for the police and National Guard to retaliate against them. Where blacks saw the riots as expressions of legitimate grievances, whites were inclined to explain them as eruptions of black hatred and senseless criminality…. To many white Americans, then, the civil disorders of the 1960s amounted to an appalling collective mugging. (Kinder and Sanders 1996, p. 104).

Liberals, then, faced the unenviable task of explaining why, after leading the fight to pass major civil rights laws, blacks appeared to be responding not with gratitude, but with annual explosions of violence, looting, and destruction.

As political analyst James Sundquist observes, the potency of law-and-order themes was evident as early as 1966, when Ronald Reagan (1911–2004) easily won the governorship of California after promising to “get tough” on welfare, crime, riots, and student unrest. In October 1966, the Republican Coordinating Committee charged that officials in the Lyndon B. Johnson (1908–1973) administration had “condoned and encouraged disregard for law and order.” In an August 29, 1967, press conference, House Republican leader Gerald R. Ford (1913–2006) proclaimed:

The war at home—the war against crime—is being lost. The Administration appears to be in full retreat. The homes and the streets of America are no longer safe for our people. This is a frightful situation…. The Republicans in Congress demand that the Administration take the action required to protect our people in their homes, on the streets, at their jobs…. There can be no further Administration excuse for indecision, delay or evasion. When a Rap Brown and a Stokely Carmichael are allowed to run loose, to threaten law-abiding Americans with injury and death, it’s time to slam the door on them and any like them—and slam it hard! (quoted in Sundquist 1983, p. 385)

As Sundquist notes, Ford’s statement illustrates that “by 1967, the Republicans were pulling out all the stops” (on the law and order issue). In 1968 “the issue was propelled by so many events that it hardly needed partisan exploitation” (1983, p. 385).

The cumulative effect of civil-rights violence, assassinations, urban rioting and unrest, the tumult at the 1968 Democratic convention, and the comparatively peaceful 1968 Republican convention in Miami was to create a climate unmistakably ripe for Republican law-and-order appeals. Many Americans were shell-shocked by the rising crime rates and domestic violence of the 1960s, amplified by the increasingly controversial Vietnam War, with anti-war demonstrators burning their draft cards and soldiers coming home, some in body bags, others maimed. In May 1970, Ohio National Guardsmen opened fire on antiwar protesters at Kent State University, killing four students and injuring nine. Many Americans sympathized more with the shooting guardsmen than with the dead students—a sentiment captured in Neil Young’s protest song “Ohio” (written immediately after the Kent State shootings and performed by Crosby, Stills, Nash, and Young).
The song characterized conservative sentiment as celebrating the shootings: "should’ve been done long ago."

**LAW AND ORDER IN THE 1968 CAMPAIGN**

The political context in 1968 was clearly ripe for a campaign centering on law and order. The Nixon campaign eagerly seized the opening. Nixon’s selection of Agnew as his running mate sent an unmistakable signal that if elected president he would “crack down” hard on rioters, draft protesters, and others perceived as contributing to or fomenting social and urban unrest. At the 1968 Republican convention, Nixon began his acceptance speech: “As we look at America, we see cities enveloped in smoke and flame. We hear sirens in the night.” Nixon’s speech continued by attacking Democratic-sponsored government programs for the unemployed, the poor, and cities as “reaping an ugly harvest of frustration, violence, and failure across the land.” Nixon’s campaign advertisements, too, reinforced the law-and-order theme. As Kinder and Sanders note:

> Nixon’s television advertisements played upon Americans’ fear of crime. While voiceovers pointed to sharp increases in violent crime and blamed the Democrats, the television viewer witnessed scenes of riots and buildings in flames, montages of urban decay, a lonely policeman on the beat, a mugging, crowds taunting the police, faces of anxious and perplexed Americans, and a woman walking alone on a deserted city street as darkness fell. (Kinder and Sanders 1996, p. 226)

After Nixon’s election victory in 1968, Agnew, as vice president, demonstrated a slashing, attack-dog speaking style that further expanded on law-and-order themes. As noted by Sundquist, Agnew toured the country to support Republican candidates, attacking and denouncing “permissivists,” “avowed anarchists and communists,” “misfits,” the “garbage” of society, “thieves, traitors and perverts,” and “radical liberals” (1983, p. 387). This rhetoric is anything but subtle in positioning the Republican Party as representing the masses of “middle America” that abide by society’s rules, are horrified by social violence, and support harsh crackdowns against it—a group that later would be targeted by the appeal of the 1972 Nixon campaign to the “silent majority.” By implication, Agnew sought to position Democrats as representing less savory elements: antiwar radicals, draft-card burners, urban rioters, black militants, hippies, and practitioners of recreational drug use and sexual activity. Agnew’s language, then, expanded the law-and-order theme to imply that Democrats sympathized not only with those who encouraged and practiced crime and violence (i.e., black militants, urban rioters, and draft-card burners), but also with groups that encouraged a more general social permissiveness and breakdown of traditional moral values—that is, permissivists, radical liberals, and perverts. These themes foreshadowed Nixon’s 1972 reelection campaign, which would successfully brand Democratic presidential candidate George McGovern as the candidate of “acid, amnesty, and abortion.”

**1972 TO 2007: LAW-AND-ORDER THEMES RECYCLED**

Since 1972, explicit law-and-order themes have become less central issues in most campaigns. However, a major exception was the 1988 presidential campaign, when George H. W. Bush portrayed Democratic candidate Michael Dukakis as “soft” on violent crime in a campaign that critics charged appealed to racial prejudices. The campaign featured the story of William “Willie” Horton, a black convict who, released from prison on a weekend furlough (a controversial program supported by Massachusetts governor Dukakis), escaped to Maryland, where he attacked a couple in their home. Republican strategists openly exploited the Horton case. One television advertisement, sponsored by an independent pro-Bush group, showed a sinister and unruly-looking Horton in a mug shot, while an announcer recounted Horton’s crimes, emphasized by the words *kidnapping, raping, and stabbing* appearing in large print on the screen. Republican strategist Lee Atwater (1951–1991) promised that “by the time this election is over, Willie Horton will be a household name.” Later, he said “the Horton case is one of those gut issues that are value issues, particularly in the South, and if we hammer at these over and over, we are going to win.” As Kinder and Sanders note, Atwater joked to a Republican gathering, “There is a story about Willie Horton, who, for all I know may end up being Dukakis’ running mate…. Maybe [Dukakis] will put this Willie Horton on the ticket when all is said and done” (1996, p. 255).

The 1988 campaign illustrates the political dangers for Democrats of not responding adequately to Republican efforts to brand them as “soft on crime.” Especially in the more conservative South, Democrats have responded by emphasizing crime-fighting credentials and support for the death penalty. Bill Clinton used this formula successfully in his 1992 and 1996 presidential campaigns, and in 2005 Democrat Timothy Kaine won the governorship of Virginia, a conservative state. Kaine successfully fended off Republican attacks on his personal opposition to the death penalty by promising to uphold death sentences handed down by Virginia juries. The law-and-order campaign theme most clearly applies to the 1968 presidential campaign. However, it has spawned similar campaign themes, usually pursued by Republicans.
eager to portray Democrats as “soft on crime,” with varying degrees of success.

LAW AND ORDER AND VIGILANTISM IN AMERICAN LIFE AND FILM

Paradoxically, the appeal of law-and-order themes has potentially contributed to citizen vigilantism at times. American history offers numerous examples of citizens “taking the law into their own hands.” White southerners’ lynchings of blacks are but one example of vigilant actions defending a social order that is anything but admirable. In 1898, for instance, the majority-black port city of Wilmington, North Carolina, was consumed by a race riot in which an unknown number of blacks (probably dozens) were murdered and hundreds more banished by an armed white mob bent on establishing white supremacy in local and statewide politics. Historian Timothy Tyson described the actions and motives of riot instigators as follows:

On Nov. 10, 1898, heavily armed columns of white men marched into the black neighborhoods of Wilmington. In the name of white supremacy, this well-ordered mob burned the offices of the local black newspaper, murdered perhaps dozens of black residents—the precise number isn’t known—and banished many successful black citizens and their so-called “white nigger” allies. A new social order was born in the blood and the flames, rooted in what News and Observer publisher Josephus Daniels, heralded as “permanent good government by the party of the White Man.” (Tyson 2006)

Tyson added that the riot “marked the embrace of virulent Jim Crow racism” nationwide. The Red Shirts, a paramilitary arm of the then-white-supremacist Democratic Party, had rampaged across North Carolina before the 1898 election, disrupting black church services and Republican meetings, and attacking blacks, who leaned Republican. These violent, vigilant actions were justified as necessary to preserve a cherished social order, white supremacy, by any means necessary. That their actions were neither lawful nor orderly probably never crossed the minds of either the Red Shirts or the white participants in the Wilmington riot.

Similarly, some anti-immigration activists along the U.S.-Mexican border have launched vigilante efforts to deter would-be undocumented immigrants from crossing from Mexico into the United States. Ranch Rescue is one such group, which styles itself as a defender of U.S. borders and private property rights against what it calls “criminal aliens” and “terrorists” out of a belief that law enforcement is unable or unwilling to act appropriately toward these ends. In 2005 Ranch Rescue founder Casey Nethercutt lost his southern Arizona ranch to satisfy a court judgment levied against him and other Ranch Rescue members for seizing and traumatizing two Mexican immigrants (Pollack 2005). The Wilmington riots and the Ranch Rescue case illustrate behaviors that are probably driven by the conviction that to restore law and order—or a cherished social goal—requires violating law and order at least temporarily.

The vigilantism inherent in the actions of the Wilmington riot instigators and Ranch Rescue members is also reflected in some American films. In movies like the Death Wish series starring Charles Bronson (1921–2003) and The Punisher (1989 and 2004), vigilantism is celebrated, with a curious and unmistakable implicit message: exacting revenge sometimes requires violating law and order—even abandoning the rule of law altogether. Law and order, then, has morphed from an often-potent political symbol from the 1960s through the 1980s to a notion that some action films celebrate violating—but whose impact in real-world politics is largely blunted.

LAW OF LARGE NUMBERS

Classical statistics assumes simple random sampling in which each sample of size n yields different values. Thus, the value of any statistic calculated with sample data (for example, the sample mean) varies from sample to sample.
A histogram (graph) of these values provides the sampling distribution of the statistic.

The law of large numbers holds that as \( n \) increases, a statistic such as the sample mean \( (\bar{X}) \) converges to its true mean \( (\mu) \)—that is, the sampling distribution of the mean collapses on the population mean. The central limit theorem, on the other hand, states that for many samples of like and sufficiently large \( n \), the histogram of sample means will appear to have a normal bell-shaped distribution. As the sample size \( n \) is increased, the distribution of the sample mean becomes normal (central limit theorem), but then degenerates to the population mean (law of large numbers). This process is shown in Figure 1. For an infinite number of samples, each of size \( n = 5 \), drawn from an exponential distribution with a mean of one, the probability density function (pdf) of \( \bar{X} \) is right skewed, but for \( n = 30 \) the pdf appears more bell-shaped, and for \( n = 90 \) it is approximately normal. As \( n \) gets larger and larger (approaching infinity) the pdf of \( \bar{X} \) appears to be a thick line at a mean of one, which illustrates the law of large numbers. Remember, however, that even as \( n \) goes to infinity, within two standard deviations of the mean there will continue to be approximately 95 percent of the distribution. It is the standard error of the mean \((\sigma / \sqrt{n})\) that keeps shrinking.

More technically, a distinction is made between the weak law of large numbers and the strong law of large numbers. The weak law of large numbers states that if \( X_1, X_2, X_3, \ldots \) is an infinite independent and identically distributed sequence of random variables, then the sample mean

\[
\bar{X} = \frac{X_1 + X_2 + X_3 + \ldots + X_{n-1} + X_n}{n}
\]

converges in probability to the population mean \( \mu \). That is, for any positive small number \( \varepsilon \),

\[
\lim_{n \to \infty} \Pr(|\bar{X}_n - \mu| < \varepsilon) = 1.
\]

The strong law of large numbers states that if \( X_1, X_2, X_3, \ldots \) is an infinite sequence of random variables that are independent and identically distributed with \( E(|X|) = \mu < \infty \), for all \( i \), then

\[
\Pr(\lim_{n \to \infty} \bar{X}_n = \mu) = 1.
\]

That is, the sample average converges almost surely to the population mean \( \mu \).

Students, scientists, and social commentators have been and continue to be befuddled by the law of large numbers versus the central limit theorem. Although the law of large numbers was articulated by Jacob Bernoulli (1654–1705) in the seventeenth century, in the nineteenth century curve fitting and the finding of normality in nature were popular. It was believed that if the sample was big enough then it would be normal (not understanding that the central limit theorem applies to \( \bar{X} \) and not to a single sample of size \( n \)). For instance, Adolphe Quetelet (1797–1874), originator of the “average man,” made his early reputation by arguing that bigger and bigger samples would yield a bell-shaped curve for the attribute being sampled. He did not make the connection between the mean of one random sample and the distribution of means from all such samples (see Stigler [1986] for this history). By the law of large numbers, the larger the sample size the more the sample will look like the population (the sampling distribution of \( \bar{X} \) appears to collapse on \( \mu \)).

To this day, confusion exists among those who should know the difference between the law of large numbers and the central limit theorem. For example, in his otherwise excellent book, Against the Gods, Peter Bernstein wrote:

Do 70 observations provide enough evidence for us to reach a judgement on whether the behavior of the stock market is a random walk? Probably not. We know that tosses of a die are independent of one another, but our trials of only six throws typically produced results that bore little resemblance to a normal distribution. Only after we increased the number of throws and trials substantially did theory and practice begin to come together. The 280 quarterly observations resemble a normal curve much more closely than do the (70) year-to-year observations. (Bernstein 1996, p. 148)

LAY THEORIES

Laypeople, like scientists, develop and use theories to help them understand and respond to their social world. Lay theories, then, are the theories people use in their everyday lives. Lay theories are often captured by proverbs such as “the early bird gets the worm” (Protestant work ethic), “you can’t teach an old dog new tricks” (entity theory), and “it’s never too late to turn over a new leaf” (incremental theory). Such lay theories often reflect the core beliefs of people living in a given culture or environment. Since the 1990s there has been greater recognition that people’s perceptions are filtered through and guided by their lay theories and thus there is not one universal way for people to perceive and respond to the same social information.

Researchers—namely cognitive, social, personality, and developmental psychologists—have identified different kinds of lay theories and their far-reaching impact on judgments and behaviors toward the self, individual others, and groups. Lay perceivers can rather easily report their lay theories, agreeing or disagreeing with simple, straightforward sentences reflecting those ideas (e.g., “people who work hard succeed”). Yet people are generally unaware of the tremendous impact that their lay theories have on them and on others, such as guiding decisions on whom to ask out on a date, what career path to choose, whom to vote for or against, and whether to befriend or avoid members of certain groups. As one example, individuals who hold the lay theory that people cannot change their personality, morality, or intelligence (e.g., entity theory) tend to give up in the face of an academic or social failure; often judge a defendant as guilty based on minimal negative information about his or her character; and frequently endorse stereotypes of socially stigmatized groups.

Lay theories are readily used in everyday life in part because they are functional. Like scientific theories, lay theories provide understanding, prediction, and a sense of control over one’s social world. However, unlike scientific theories, lay theories need not be objective, testable, or true. Lay theories serve people’s needs to label their observations as reflecting a correct social reality. Lay theories such as the Protestant work ethic can fulfill important values (e.g., value of hard work). People may use lay theories as well to justify their attitudes and prevailing social norms. For example, the Protestant work ethic is an ingredient in racism toward African Americans at the hands of European Americans in the United States; African Americans are sometimes seen as not conforming to the work ethic (not working hard enough) and thus deserving disadvantage. Some lay theories may serve many cognitive, social, and psychological functions, and other lay theories may serve only one. What is more, some lay theories are more or less useful to certain members of a culture (e.g., relatively advantaged or disadvantaged group members) or more or less useful in certain contexts (e.g., at home or at work).

In summary, lay theories have far-reaching implications for understanding how people work. Lay theories can both drive and justify thought and behavior that impact the self and others.

LAZARSFELD, PAUL FELIX

1901–1976

The Austrian sociologist Paul Lazarsfeld studied law, social psychology, and mathematics at the University of Vienna under the direction of Ernst Mach, physicist and founding figure in the field of philosophy of science. Lazarsfeld received his PhD in applied mathematics in 1925. In 1929 he founded a research institute for applied social psychology connected with Karl Buhler’s research center in Vienna, then moved to the United States on a Rockefeller Foundation grant in 1933. While at Princeton
University directing the Office of Radio Research, Lazarsfeld studied the listening habits of radio audiences, the first of many studies on the media and public opinion. In 1940 he moved to Columbia University in New York to direct the Bureau of Applied Social Research, where he conducted extensive empirical social research and later joined the sociology department. At Columbia University Lazarsfeld collaborated with prominent sociologists such as Robert Staughton Lynd (1892–1970) and Robert K. Merton (1910–2003). Lazarsfeld continued to work at Columbia University until 1970, when he moved to the University of Pittsburgh, where he taught until his death in 1976.

Along with Albert Einstein (1879–1955), Enrico Fermi (1901–1954), Max Horkheimer (1895–1973), Theodor Adorno (1903–1969), and Niels Bohr (1885–1962), Lazarsfeld was part of an intellectual migration of academics from Europe during the early stages of Nazism. Many moved to the United States where they conducted research free from government interference and created a wealth of intellectual activity in U.S. universities.

Lazarsfeld’s research in the field of sociology, particularly in the areas of social and applied psychology, used statistics to determine the influence of radio and print media on Americans’ voting habits and personal preferences. Concerning himself with the development of empirical social science methods, Lazarsfeld applied his background in mathematics in the field of sociology, conducting independent and corporate-funded research on public opinion, voting, and popular culture. Written contributions to the field of empirical social science and survey research include The People’s Choice (1944), with Bernard Berelson and Hazel Gaudet, a study of how public opinion was formed prior to elections; Radio Listening in America (1948), an analysis of radio listening habits; and Voting (1954), with Berelson and William N. McPhee, an inquiry into the determining factors of candidate selection. These publications placed Lazarsfeld’s Bureau for Applied Social Research at the forefront of postwar American sociology.

Lazarsfeld is considered a pioneer in the field of media research. His research, both quantitative and qualitative, provided a scientific framework to study media influence on political attitudes. Lazarsfeld’s research on radio listeners and the effect of radio listening on public preferences was used by market researchers, pollsters, and political campaigns to better understand the relationship between popular culture and public tastes. One of the first to systematically study the media, Lazarsfeld’s research influenced mass communications theory, survey research, public opinion, and polling. In his theory of the two-step flow, Lazarsfeld explained how media information flows from opinion leaders to the larger public. He is also credited with introducing the concept of agenda setting, which was further developed by a later generation of social theorists. His empirical social analysis was later criticized by C. Wright Mills in The Sociological Imagination (1959). Lazarsfeld is credited with educating a generation of sociologists and bringing the academic discipline of sociology into the modern era, incorporating social and applied psychology and mathematics into the field to solve substantive sociological problems.

Leaders

Leadership is influencing the performance of group members toward the achievement of organizational goals through persuasion, example, direction, control, or oversight. There are two inherent conflicts in the very idea of leadership in a democratic society. The first is embodied in the British statesman and orator Edmund Burke’s (1729–1797) distinction between employing one’s own best judgment in service of constituents (a trustee), and trying as assiduously as possible to implement the will of
the majority, regardless of whether it seems right to the “leader” (a delegate):

Your representative owes you, not his industry only, but his judgment; and he betrays, instead of serving you, if he sacrifices it to your opinion (“Speech to the Electors of Bristol,” November 3, 1774, reprinted in Laski, 1998).

This point is deeper than the indeterminacy of the social choice problem, raising instead a paradox in the nature of leadership itself. There is a distinction, dating back at least to Plato, between *rulers* (members of an elite, born and socialized to rule by virtue of merit), and *leaders* (people chosen by the people from among themselves). If decisions are truly democratic, why does a society need leaders in the first place?

An interesting example of the tension between leading the people and simply implementing their will can be found in the October 1944 diary of British member of Parliament Sir Cuthbert Headlam (1999, entry for 10/12/44): “Never was a party so leaderless as the Conservative party is today.” What leader was it that Sir Headlam held in such low esteem? Winston Churchill, perceived by history as one of the great wartime leaders of all time. But in terms of advancing the fortunes of his party, Churchill either did not care or could not be bothered. Who was right: Headlam or history? In voters’ minds, Headlam’s view was correct. Churchill was unceremoniously dumped from office, with his Conservatives so resoundingly defeated in July 1945 that the opposition Labour Party gained a majority of more than 180 seats.

The second inherent conflict divides transactional leadership and transformational leadership. Transactional leadership is close to Taylorist principles of management and control, focusing on mechanism design and incentive compatibility, assuming that rewards and punishment motivate workers. The successful transactional leader compensates workers in a strict hierarchy in exchange for their service to the collective goal.

Transformational leaders begin with a vision, and persuade subordinates to share that vision. Inspiration, rather than either direction or control, is the objective. Transformational leaders believe that success comes first and last through deep and sustained individual commitment among followers.

These two distinctions suggest the following schematic representation of leadership.

It is useful to consider in more detail two accounts of charismatic leadership that have had a large impact both in the training of leaders and in the academy. The first of these is by the German social theorist Max Weber; the second is the work of contemporary management theorist Bernard Bass.

**THEORIES OF CHARISMATIC LEADERSHIP**

Weber believed that there are three types of systems in which leadership matters. The first is traditional/feudal; the second is charismatic leadership; and the final type, the highest achievement of leadership in an evolutionary sense, is the legal/rational leader, whose authority is based on expertise, experience, and technical training.

Traditional leadership authority is based on tradition and patriarchy, suppressing conflict but substituting an irrational and capricious order. Government actions arbitrate competition among those seeking favors, income, and other advantages, with leaders personally collecting fees. This system allows for some mobility among the classes, but the actual functions of government are based on loyalty, not merit.

Charismatic authority derives from the exceptional sacrifice, heroism, or exemplary character of the leader. Claims to charismatic authority are bolstered by assertions of destiny, being “chosen” or selected, or other supernatural signs. But pure charismatic leadership does not rely, or even allow, any other administrative or governmental organizations. If an organization relies on charismatic leadership, it may collapse into chaos if the leader dies or leaves, because subordinates act out of personal regard for that individual leader rather than the organization as an abstraction.

</tr>
</tbody>
</table>
The highest expression of the potential for leadership authority, for Weber, was rational/technical/legal authority. Weber argued that bureaucracy is “the exercise of control on the basis of knowledge” (1947, p. 339). The leader is controlled and disciplined by rules and procedures, and open commitment to these procedures is the entire basis for the leader’s authority. The office holder is constrained to impersonal, official obligations and commands, and cannot benefit either directly or indirectly from decisions. In the hierarchy of offices, it is office holders, not persons, who exercise authority. Real leadership requires extensive training and demonstrated expertise and experience. Deference and obedience are owed not to individuals, but to the impersonal order.

Bass accepted many of Weber’s claims, but adapted for his own purposes the idea of charismatic rather than legal/rational relations among leaders and subordinates. In his Leadership and Performance Beyond Expectations (1985) Bass began with what seems like a paradox, from the perspective of Weberian or Taylorist perspectives on leadership. Why is it that most leaders are able to elicit only competent performance from employees? Why are some leaders able to elicit much more, and to make the workers happier and more fulfilled at the same time?

The explanation Bass offered is that the transactional, contractual approach described by Weber, and the charismatic leader Weber admired but considered anachronistic, could be combined into a new synthesis. Truly successful leadership depends on charisma, and successful organizations must nurture and promote charismatic individuals to leadership positions.

Bass created a taxonomy of personalities in an organization. The mix of personalities on teams, and the profile of the leader, might have as much to do with the success of the team as the abilities of the team and the technical nature of the task. He calls the three personality types self-oriented, task-oriented, and interaction-oriented. Task-oriented personalities are self-sufficient, resourceful, competitive, and motivated by intellectual challenges if they are not distracted. Self-oriented personalities are disagreeable, introverted, and often jealous, but they can be motivated by their desire for personal success and rewards. Interaction-oriented personalities are motivated by contact and interaction with others, and have much lower needs for autonomy or personal rewards.

Bass claimed that charismatic, transformational leaders could have an unexpectedly large impact on nearly any organization, so long as they consciously focused on three things. First, subordinates must be made to feel aware of the importance of their tasks and the importance of performing well. Part of this “importance” rests in expectation of reward, but much of it could simply be expectation of recognition and respect.

Second, Bass argued it was important to make subordinates aware of their needs for personal growth, development, and accomplishment. That is, the specific tasks being worked on today might be less important, both to the individual and the organization, than the impact that task might have on the employee’s career. Finally, Bass claimed that transformational leaders must motivate their subordinates to work for the good of the organization rather than exclusively for their own personal gain or benefit. This might be achieved by making subordinates feel they belong, or can depend on each other, in a variety of ways, but the important thing is reconciling collective goals and individual fulfillment.

LEADERSHIP
The study of leadership is not only a search for understanding the thoughts and actions of leaders, but also an investigation into how to improve the performance and motivation of both individuals and groups. Given the importance of leadership to the success of groups, organizations, or even entire civilizations, there are few more pressing questions than, “What is leadership?” Attempts to answer this question are evident in early discussions of the notion of leaders. Governments, businesses, industries, and private organizations have all turned to behavioral scientists to better understand how organizations work efficiently, how managers can improve workers’ performance, how teamwork and commitment can be instilled, and how an environment conducive to change can be structured.

DEFINING LEADERSHIP
The notion of leadership “connotes images of powerful, dynamic individuals who command victorious armies, direct corporate empires from atop gleaming skyscrapers, or shape the course of nations” (Yukl 2002, p. 1). Yet, considerable debate exists among researchers regarding an understanding of who exerts influence, what kind of power or influence is exerted, when and where leadership takes place, and why and how this phenomenon occurs.
Leadership

As many definitions of leadership exist as do authors who have studied the concept. Conceptions and definitions of leader and leadership have been reviewed by Carroll Shartle (1956), Bernard Bass (1960), and James Hunt and colleagues (1982), among others. Some of the more recent definitions focus on influence, collective understanding, effectiveness, and facilitation:

- “Leadership appears to be a working relationship among members in a group, in which the leader acquires status through active participation and demonstration of his or her capacity to carry cooperative tasks to completion” (Bass and Stogdill 1990, p. 77).
- “Leadership is a process of giving purpose [meaningful direction] to collective effort, and causing willing effort to be expended to achieve purpose” (Jacobs and Jaques 1990, p. 281).
- “A definition of leadership that would be widely accepted by the majority of theorists and researchers might say that ‘leadership is a process of social influence in which one person is able to enlist the aid and support of others in the accomplishment of a common task’ ” (Chemers 1997, p. 1).
- “Leadership is influencing people—by providing purpose, direction and motivation—while operating to accomplish the mission and improving the organization” (Department of the Army 1999, pp. 1–2).

The common thread in the majority of definitions is that leadership is an active process of one person exerting influence over one or more other persons toward a common goal or objective. However, the similarities end there, and leadership definitions do not always fit into the applications for which they are used. For example, Bernard Bass and Ralph Stogdill’s definition of leadership does not fully account for hierarchical structures, and T. Owens Jacobs and Elliot Jaques’s definition does not address the interactive nature of leadership between a superior and a subordinate. A more adequate definition of leadership needs to account for both the individual person and the situational context. The definition provided by the U.S. Army is comprehensive and useful. Therefore, this entry also defines leadership as “influencing people—by providing purpose, direction and motivation—while operating to accomplish the mission and improving the organization” (U.S. Army 1999, pp. 1–2).

Having defined leadership, it is necessary to examine assumptions about the topic. Some commentators assume that certain individuals are predisposed to be leaders, while others are not. If the person is the most important predictor of leadership success, then personnel selection matters most. However, other scholars assume that context is most important in developing leaders. If the situational variables are the most influential aspects of leadership success, then the training models employed would seem most important. A review of the historical approaches to leadership will highlight these two divergent approaches.

A REVIEW OF THE HISTORICAL STUDY OF LEADERSHIP

An understanding of the historical literature and the changing philosophies behind leadership studies add meaning and depth to current integrated theories. The concepts examined provide a framework for understanding current models and examining future directions.

Traits and Attributes Theories Few areas of research have had a more controversial history than that on leadership traits and attributes. One question that researchers have tried to answer is “who is exerting the influence?” During the nineteenth and early twentieth centuries, “great man” theories dominated leadership discussions. The great man concept suggested that leaders possessed special traits or characteristics that allowed them to ascend above others and enhanced their ability to be leaders (Hollander and Offermann 1990b). This view is often linked to the nineteenth-century philosopher Thomas Carlyle, who wrote “the history of the world is but the biography of great men” (1841). In short, the attributes of effective leaders were seen as inborn and permanent, and they applied to various circumstances. Later, Francis Galton expounded on this concept in Hereditary Genius (1869), where he argued that reputation flows from heredity.

The great man theory led to hundreds of research studies that looked at personality traits, physical characteristics, intelligences, and values to differentiate leaders from followers. In the early 1900s, psychologists developed intelligence testing to measure individual differences in analytic ability. Initial findings that intelligences correlated with leadership led researchers toward searching for additional nonintellective traits that might be predictors of behavioral tendencies (Chemers 1997).

Ralph Stogdill was the first researcher to summarize the results of these studies. He examined 124 studies to determine the characteristic differences between leaders and followers. He came to two major conclusions. First, Stogdill found slightly higher intelligence measures for leaders, as well as positive relationships between leadership and adjustment, extroversion, and dominance. However, Stogdill failed to find traits that were universally associated with leadership and could be reliably used to predict who might be an emerging leader. Stogdill concluded that “a person does not become a leader by virtue of the pos-
Leadership

session of some combination of traits” (1948, p. 63). Later, Richard Mann (1959) came to the same conclusions that although individuals with certain characteristics were more likely to be successful leaders, leaders were not altogether different from followers. As a result, later researchers erroneously concluded that personal traits and attributes alone could not be used to predict future leadership success.

It was not until the publication of a meta-analysis by Robert Lord, Christy de Vader, and George Alliger (1986) that such traits as intelligence and personality regained favor with leadership researchers. Their article reexamined the relationship between personality traits and leadership perceptions and emergence. In contrast with the conclusions of earlier nonquantitative literature reviews on traits and leadership, Lord and his colleagues utilized the literature investigated by Mann in his 1959 review and subsequent relevant studies and found that prior research on trait theories was misinterpreted as applying to leader effectiveness when it actually applied to the relationship between leader traits and leader emergence. Using meta-analytic techniques, their results supported social perception theories where several traits were expected to be related to leadership perception. Specifically, they found that intelligence, masculinity-femininity, and dominance were significantly related to followers’ perceptions of their leader’s effectiveness. Shelley Kirkpatrick and Edwin Locke (1991) found that successful leaders’ traits include drive, the desire to lead, honesty and integrity, self-confidence, cognitive ability, and competence. Overall, as the study of traits and attributes in relation to leadership continued, the beginnings of the study of leadership as a behavioral phenomenon began.

Behavioral Theories After World War II (1939–1945), researchers emphasized the observable aspects of leadership in order to differentiate not only the nature of leadership and leader activity but also the behavioral patterns of effective leaders (Chemers 1997). A research program at Ohio State in the 1940s attempted to measure leadership behavior as group members described the behavior of the leader. From this data, John Hemphill (1950) quantified 150 behavior descriptors that were incorporated into the Leader Behavior Description Questionnaire (LBDQ), which is still used as a measure in leadership research. Andrew Halpin and Ben Winer (1957), while adapting the LBDQ for use in the U.S. Air Force, identified initiating structure and consideration as two fundamental dimensions of leader behavior. Earlier, Daniel Katz and Robert Kahn (1966) had attempted to identify general styles of leadership. From interviews with subordinate employees or “followers,” they recognized two general styles: production-oriented and employee-oriented. The former is focused on planning, preparation, direction, and end-state productivity. In contrast, employee-oriented leaders identified with followers, exemplified openness, and showed concern for the well-being of subordinates.

With the limitations of behavioral approaches for explaining why some leaders are more effective than others, leadership researchers shifted their focus away from what leaders are toward developing a better understanding of what leaders actually do, and how such behaviors relate to leader effectiveness (i.e., how often a leader communicates with followers, what types of reward and discipline methods he or she uses, and the decisions leaders make).

Although behavioral approaches to leadership generated great interest, they also generated a number of controversies, including accusations of inconsistencies in findings (Bass and Stogdill 1990). For example, there are significant variations in most relationships between leadership styles and behaviors and the various indicators of leadership effectiveness, such as morale and satisfaction (Bryman 1992). These inconsistencies in the literature instigated the emergence of contingency approaches to leadership to account for differences found across situations.

Contingency and Situational Theories Contingency and situational theories examine both the tasks and the follower characteristics to specify what behavior is required of effective leaders. The circumstance in which leader-follower interaction takes place plays a major role in the process of leadership. Captured in the situational leadership approach are the quality of relationships, tasks, and activities to be performed, perceptions of the leader based on history, the motivation of both the leader and the follower, and personal characteristics influencing the situation. There exist several contingency and situational theories, but perhaps the most commonly researched were F. E. Fiedler’s (1967) contingency theory of leadership, Paul Hersey and Kenneth Blanchard (1969) situational leadership model, Robert House’s (1971) path-goal theory of leadership, and Victor Vroom and Philip Yetton’s (1973) normative decision model.

Fiedler’s contingency model proposes that leader effectiveness is a function of the match between the leader and specific situational factors, including position power, task structure, and leader-member relations. Fiedler’s model differentiates between task-oriented and relationship-oriented leadership styles, but also measures ratings of the person with whom employees are least able to work. Fiedler found that the effectiveness of the leader-follower interaction was contingent upon the factors of leader-follower relationship, task structure, and leader position. If these factors were all high or all low, it was determined that a task-centered leader would be most effective. However, if the factors were mixed, an employee-centered leader was found to be most effective (Fiedler 1967).
Further, Fiedler argued that leaders cannot adjust their behavior to changing circumstances. If a leader's style is not appropriate for the specific situation, the leader will not be successful and an organization must change the leader. However, most contemporary theorists believe that leaders can adjust their style. If that is so, what should leaders consider in making adjustments?

Hersey and Blanchard's situational leadership model sought to answer this question. There was little evidence to support a relationship between leader behavior and leader effectiveness. Instead, the relative effectiveness of these two elements often depended on the context of the task. Hersey and Blanchard used the terms task behaviors and relationship behaviors and sought to explain why leadership effectiveness varies across these two dimensions. In their model, they depicted task behavior and relationship behavior as orthogonal dimensions. They argued that this approach is useful because certain combinations of task and relationship behaviors may be more effective in certain situations than in others.

Another contingency model deals with different aspects of leader-follower relationships. Path-goal theory is based on the idea that it is the leader's responsibility to clarify the path, remove obstacles, motivate his or her followers, and provide feedback to achieve organizational goals while setting guidelines on how to accomplish those goals. Path-goal theory examines the contingency of the leader's effectiveness at increasing a subordinate's motivation along a pathway leading to a certain goal. House proposed three areas that would affect the path-goals relationship: the task, the characteristics of the followers, and the nature of the group to which the followers belong. The theory hypothesizes that certain subordinates will respond better to directions when a task is unstructured (e.g., developing building plans) than when a task is structured (e.g., air traffic controlling) (House and Dessler 1974). The response is contingent upon differences in both the individual and the task. More importantly, understanding the effects of the nature of the task should influence how leaders behave.

Another influential model within the contingency approach is the normative decision model from Vroom and Yetton. In this model, emphasis is placed on increasing followers' involvement. The leader's method of including followers is contingent upon such constraints as time, talents, and resources. Another important aspect of the model is to what extent the support of followers is critical to successful outcomes. The implications of this model are that leaders who possess an awareness of their subordinates' involvement can improve the decision-making process.

All of these models have helped to develop an understanding of leadership complexities. Although contingency theories dominated leadership research for decades, a number of writers have questioned the methods used to tests these theories (Yukl 2002). For example, J. C. Wofford and Laurie Liska (1993) quantitatively reviewed 120 path-goal studies and found that only seven of the moderators used were significant. Katherine Miller and Peter Monge (1986) meta-analyzed research on the effects of participation in decision making on satisfaction and productivity. Results failed to support the contingency model predictions.

**Transactional Theories**

Transactional models describe a process-oriented exchange between leaders and followers. As Edwin Hollander and Lynn Offermann (1990a) explained, transactional models focus on the follower's perceptions of the leader's actions. The concern for process stems from the social exchange between leaders and followers as a function of effectiveness (Shaw and Costanzo 1982). These models emphasize persuasive influence instead of compelled compliance. Hollander developed a transactional leadership model, and in its context coined the term *idiosyncratic credit*. Idiosyncratic credits are often defined as a tit-for-tat exchange. Hollander (1958) explained that leadership was a social exchange transaction between leaders and followers where “legitimacy” was the currency of the exchange. To have a successful transaction, the leader must provide direction, guidance, and technical knowledge, as well as recognition of followers' inputs. In turn, followers increase their receptiveness and add legitimacy to the leader's influence (Hollander 1993).

By demonstrating competency, assisting the achievement of group goals, and conforming to group norms, leaders demonstrate commitment to the group and in turn earn credits (Chemers 1997). By obtaining credits, the leader gains latitude to explore new and perhaps non-normative ideas, methods, and courses of action, all of which can potentially lead to innovations. Overall, the successful employment of the idiosyncratic credit exchange leads to legitimacy in shaping the perceptions of subordinates. In a cyclical nature, from the leader-follower exchange, group performance is increased (Green and Mitchell 1979).

Other relationship- and influence-oriented theories include *implicit leadership theory*, leader-member exchange theory, and *Pygmalion* theory. According to implicit leadership theory, a leader's behavior will not be effective unless the person is perceived as a leader (Calder 1977). Leader-member exchange theory (Green and Ginsburgh 1977) proposes that leaders have *in-groups* of trusted individuals within their organization. Subordinates in the *out-group* are supervised through a more formal authority process. Another approach is referred to as Pygmalion
theory. A critical component of this theory is the self-fulfilling prophecy, which suggests that raising leader expectations regarding follower achievement produces an improvement in the followers’ performance (Eden 1990). Over nearly three decades, researchers have found that if leaders have confidence in followers and set high goals and expectations for them, then the followers’ likelihood of success is higher due to a self-fulfilling prophecy effect (see Eden et al. [2000] for a review of this literature).

From a theoretical perspective, a common complaint against these theories is their lack of generalizability to women and to established work groups (White and Locke 2000). For example, several Pygmalion studies, with the exception of D. Brian McNatt’s (2000) meta-analysis, have reported weak effect sizes when controlling for gender (Eden et al. 2000). Indeed, McNatt reported significant differences in the effect sizes across different leadership contexts, with the results stronger in the military, with men, and for followers for whom low expectations were initially held.

R. E. Kelly (1988) brought attention to the active role of followers in achieving group success. He argues that a prerequisite to effective leadership is followership. Effective followers are “intent on high performance and recognize that they share the responsibility for the quality of the relationship they have with their leaders” (Potter et al. 2000, p. 130). The study of followership includes an understanding of two separate dimensions of follower initiative: performance and relationships. Successful organizations that have the ability to change in positive directions have leaders who value and encourage partners, and followers who seek to become partners (Potter et al. 2000).

The relationship and influence theories have furthered scientific understanding of the leadership phenomena. They have also assisted in answering the question, “Can we develop leaders?” However, these theories do not address the most pressing questions. For example, how do leaders build more enlightened and transformational forms that create referent effects beyond mere legitimacy? Modern theories have sought to explain these challenges. These more recent ideas are examined under the umbrella of new-genre theories.

**New-genre Theories** New genre refers to theories that have dominated leadership research since the 1980s, including charismatic, inspirational, transformational, and visionary leadership (Bass 1998; Bryman 1992). New leadership approaches emphasize symbolic leader behavior, visionary and inspirational messages, emotional feelings, ideological and moral values, individualized attention, and intellectual stimulation. Charismatic and transformational leadership theories have turned out to be the most frequently researched theories since the early 1990s (Judge and Piccolo 2004), with the accumulated research showing that charismatic and transformational leadership is positively associated with leadership effectiveness and a number of important organizational outcomes across many different types of organizations, situations, levels of analyses, and cultures (see Avolio, Bass, Walumbwa, and Zhu [2004] for a summary of this literature).

Hollander and Offerman described transformational leadership “as an extension of transactional leadership, but with greater leader intensity or follower arousal” (1990a, p. 88). The study of transformational leadership is rooted in Max Weber’s (1946) notion of a leader. In this theory, leaders are seen as active transforming agents, changing the outlook and behavior of their followers (Burns 1978). Transformational leaders may employ one or more of the core competencies of transactional leadership to obtain greater outcomes.

Factor analytic studies have recognized four key components of transformational leadership (Bass 1985; Avolio and Howell 1992): (1) charismatic leadership or idealized influence; (2) inspirational motivation; (3) intellectual stimulation; and (4) individualized consideration. Transformational leaders act as role models to their subordinates. The use of power is a last resort for a transformational leader. Transformational leaders motivate and inspire subordinates by providing meaning and challenge through emphasis on teamwork. Inspirational motivation leads to internalization. Leaders ensure an open exchange of ideas by allowing mistakes, soliciting new methods for problem solving, and evaluating followers’ processes rather than just situational outcomes. The leader acts as a coach, teacher, and mentor for each subordinate, providing individual attention and feedback, both positive and negative (Bass 1996).

Components of transformational and transactional leadership principles are incorporated into training strategies used by governments, corporations, and sports teams. As a result of training and education, transformational leaders motivate and enable followers to accomplish more than what is expected, set increasingly higher goals, and achieve higher standards. Transformational leadership is particularly evident in successful teams when coaches increase performance by providing motivation and inspiration. In contrast, current research on in extremis leadership, or leadership of teams facing death (e.g., fire departments, SWAT teams, and the military) shows that the environment itself provides the inherent motivation. Therefore, leaders in these extreme environments focus on continual learning and shared risk to build competency, loyalty, and trust (Kolditz 2007).

Like transformational leadership, the concept of charismatic leadership is an outgrowth of Max Weber’s
Leadership

A description of a form of influence based on follower perceptions that the leader possesses certain enviable characteristics. Weber proposed that charisma can occur when a leader with certain qualities emerges during a crisis to propose a new vision (Weber 1946). Charismatic leaders exert enormous power and influence over followers, especially followers searching for direction or for guidance during times of crisis. Leadership is considered charismatic when it “inspires the follower with challenge and persuasion, providing a meaning and understanding” (Bass 1996, p. 5). Robert House (1977) developed a theory of charismatic leadership based on the premise that charisma has a distinct effect on followers. Charismatic leaders tend to be self-confident and achievement-motivated; they also desire to assert influence, and they possess strong convictions. These types of leaders advocate change and are able to mass followers in support of their own vision. Other theories centering on charisma focus on attributes (Conger and Kanungo 1987), self-concept (Shamir et al. 1993), and social contagion (Meindl 1990).

One of the latest new-genre approaches to leadership is the framework proposed in authentic leadership theory (Gardner et al. 2005; Avolio and Gardner 2005; Avolio, Gardner, Walumbwa, et al. 2004). This theory holds that high levels of leader self-awareness, self-regulation, and transparency, among other things, will increase the leader’s positive effects on their followers. Another current approach to understanding leadership evaluates the unique characteristics of leaders in life and death situations or in extremis leaders. These leaders demonstrate inherent motivation, continuous learning, shared risk, common lifestyle with their followers, competency, trust, and loyalty (Kolditz 2007).

A 2004 meta-analysis by Avolio and colleagues compared studies in which the researcher manipulated new-genre leadership with studies that manipulated traditional theories (e.g. behavioral, trait, or contingency theories) (Avolio, Reichard, Hannah, et al. 2004). Results showed that new-genre approaches to leadership had appreciably larger effects than those based on traditional leadership theories for both affective and cognitive dependent variables, while traditional theories had a slightly larger effect on more proximal behavioral outcomes. These findings appear consistent with the core focus of these theories. New-genre theories, such as transformational leadership, are believed to have strong affective and cognitive components, and they are thus positively linked to such dependent variables as liking, trust, or intellectual engagement. Conversely, research on contingency and other more transactional leadership approaches has focused more on short-term behavioral change.

Studies suggest that researchers will continue to examine leadership in search of both an understanding of the thoughts and actions of leaders and improvements to organizational performance and motivation.

Leadership, Contingency Models of

One of the earliest theories of leadership that deliberately included features of the situation was proposed by the Austrian-born American psychologist Fred E. Fiedler (1967). According to Fiedler’s contingency model of leader effectiveness, the performance of a group is a joint function of the style of the leader and key attributes of the context. Broadly stated, the model identifies appropriate “matches” of different leadership styles for particular types of situations.

Fiedler characterized leader style as varying across a single dimension of socioemotional orientation versus task orientation. Socioemotional orientation denotes a leader who is primarily concerned with maintaining positive social relations, whereas task orientation denotes a leader who is primarily concerned with task structure and accomplishment. This stylistic orientation is assessed by having a leader complete a “least preferred coworker” (LPC) attitude scale. Comparatively high (or lenient) LPC scores are interpreted as an indication of a socioemotional orientation, while low (or harsh) LPC scores are interpreted as an indication of a task orientation. The assumption that a social-relations orientation and a task orientation are opposite ends of a single continuum differs from other popular approaches to conceptualizing leader style (e.g., the Ohio State University–based conceptualization of consideration and structuring proposes two independent dimensions of leadership style).

Situations are judged in terms of how much control they afford the leader. High-control situations are those that provide a leader with strong subordinate support, clear task structure, and substantial power that is tied to the leader’s formal position. The model posits that in extremely high-control situations and extremely low-control situations, leaders who are low LPC (i.e., task oriented) will be more effective than high LPC (i.e., socioemotional oriented) leaders. For more intermediate-control situations, the ordering of leader effectiveness is reversed, and high LPC leaders are predicted to be comparatively more effective. The precise underlying social process that might explain this pattern of association has been a major topic of study throughout the model’s history.

Fiedler developed his model from data collected over a large number of work groups in a great variety of settings. As the results of these studies were used to induce the model’s principles, subsequent research efforts have attempted to verify the proposed interaction of leader style and leader circumstance. By and large, these later attempts at verification have met with mixed success. Meta-analytic efforts (designed to summarize results across many studies) do suggest the model may be valid in certain extreme combinations of subordinate support, task structure, and leader position–based power (Peters et al. 1985). However, the magnitude of these effects for the observed associations of LPC with group performance in specific situations is not great. Moreover, there is some evidence that performance may actually decrease as situational control decreases (Schriesheim et al. 1994; Vecchio 1977). This suggests that performance may be maximal (and, therefore, situations should be created) where high LPC leaders are located within settings of extremely high situational control (i.e., positive leader-subordinate social relations, maximum task structure, and strong leader position power). Because much prior research has focused on within-setting comparisons of leaders, this across-setting comparison deserves further study.

Despite these concerns, Fiedler’s contingency model of leadership is important for its emphasis on the interplay of leader style and the situation, and its suggestion that, in some settings, it may be more reasonable to modify or engineer the situation to fit the leader’s personality, rather than attempt to modify the leader’s style.

LEAGUE OF NATIONS

The League of Nations, inaugurated in 1920, was the first major international organization to attempt to tie individual nation-state security to international security. Envisioned as a collective security—rather than a collective defense—organization, the League of Nations attempted to replace individual nation-state self-interest with an altruistic vision of international justice and cooperation. In a first for international law, the Covenant of the League committed every signatory to settle disputes through arbitration before going to war. The centerpiece of the League Covenant was Article 10, which bound the League to collectively preserve “the territorial integrity and existing political independence of all Members.”

Despite its all-encompassing mandate to preserve peace and security of the international community through mutual action, the League was not the first international organization to espouse such goals. The Concert of Europe (1815–1900) and the two Hague Conferences (1899 and 1907) had each in their way advanced the issue of international cooperation on the world stage, but both had serious limitations. The Concert of Europe was limited by the fact that only the Great Powers of Europe took part, and its means of conflict resolution (arbitration) only worked as long as each power agreed to submit. For their part, the two Hague Conferences were more inclusive (twenty-six and forty-four states, respectively) and accomplished more with respect to codifying into international law the peaceful settlement of disputes. The three Hague Conventions that arose from these conferences, along with the Permanent Count of Arbitration, presaged the Covenant of the League of Nations.

The League was born out of the experience of World War I. Many politicians believed the war had occurred in large part due to the brutal nature of realpolitik and the secretive diplomacy and shifting alliances between the Great Powers. For Woodrow Wilson, president of the United States from 1912 to 1920, the League of Nations represented a capstone of a morally based foreign policy; one designed to replace the dangerous balance of power politics with a more transparent and cooperative system between sovereign, democratic states governed by the principle of national self-determination. Wilson articulated his vision several times during his presidency, but his most famous statement on the League concluded his famous Fourteen Points speech presented before the U.S. Congress on January 8, 1918: “A general association of nations must be formed under specific covenants for the purpose of affording mutual guarantees of political independence and territorial integrity to great and small states alike.”

The League was an integral part of the Treaty of Versailles, negotiated in early 1919 and enacted on January 10, 1920. The League began operations in Geneva, Switzerland, with Sir Eric Drummond its first secretary general. Structurally, the League consisted of a council, an assembly, and a secretariat—a structure that would subsequently serve as the model for the United Nations. The Council was originally designed to have nine members: the five great powers (Britain, France, Italy, Japan, and the United States with permanent seats, as well as four temporary rotating members (the first four were Belgium, Brazil, Greece, and Spain). However, despite an ardent cross-country campaign by Wilson, which eventually contributed to his debilitating stroke, the isolationist Senate failed to ratify the treaty and the United States never officially joined the League. Thus, the Council consisted of eight members until 1922, when two additional small states were added. In 1926 the Council was further increased to fifteen members, including Germany.

The foremost goal of the League was the prevention of another world war, and the League Covenant included calls for disarmament and dispute resolution through arbitration in the International Court or inquiry before the League Council. The central focus of the Covenant was the set of articles outlining the principles and responsibilities of collective security. Article 16 declared that any state that went to war without first vetting disputes through the League processes would be deemed to have committed an act of war against all other member states of the League. Building upon the idea of deterrence through the threat of “all against one,” the collective members were then expected to sever all trade and financial relations with the aggressor state. Notably member states were not legally obliged to apply military sanctions, although Article 16 claims that military sanction may be “a political and moral duty incumbent to states.” The League’s architects, including Wilson, believed that this collective security system would ultimately preemp the precarious alliance behavior and arms races that had caused war repeatedly in the past.
The League did enjoy numerous successes, particularly in settling territorial disputes such as those between Albania and Yugoslavia (1921), Germany and Poland over Upper Silesia (1922), and Greece and Bulgaria (1925). Yet it is largely the League’s spectacular failures that stand out when accounting for its fate. Conventional wisdom holds that the refusal of the U.S. Senate to ratify the Treaty of Versailles crippled the League from the outset. Other reasons for failure are both structural and operational. Reflecting its origins as an international organization with members of varying power and interests, the League Covenant contained structural compromises needed to ensure member state ratification and participation. The biggest of these concessions was the discrepancy between Articles 5 and 10. Article 10 promised collective preservation of territorial integrity and political independence of all member states, whereas Article 5 required all decisions taken by the League Council be made on the basis of unanimity of the members in attendance. Article 5 thus ensured a veto for any member of the Council who undertook aggressive action against another member.

Operationally the League was hampered throughout its existence by the reluctance of its member states to intervene in international disputes and apply collective security mechanisms. One of the most egregious cases was the League’s weak response to Japan’s invasion of Manchuria in 1931. Instead of sanctioning Japan, the League failed to take decisive action for more than seven months—partly due to the structural flaw of the League Council, which enabled Japan (as a permanent member) to delay League action. The League finally sent observers, but only after Japan formally withdrew from the League. By 1934 the League’s lack of teeth would become readily evident again in the case of Italy’s invasion of Ethiopia (which solicited only a weak set of economic sanctions on the part of the League) and Adolf Hitler’s obvious rearming of Germany. Ultimately, the declaration of World War II—which the League was designed to prevent—spelled the demise of the institution. Although the League lingered on through the war, it finally faded into irrelevance and its functions were formally turned over to the newly created United Nations in 1945.

LEAKEY, RICHARD

1944–

Born into a family with a legacy of seeking out the origins of humankind, Richard Erskine Leakey was the second of the three sons of Louis Leakey (1903–1972) and Mary Leakey (1913–1996). Both of Leakey’s parents were renowned for their archaeological finds and influenced future generations of Leakeys toward the study of human origin. Louis Leakey had been born in Nairobi, Kenya, to missionary parents. Young Louis learned the culture, language, and traditions of the Kikuyu people and was even initiated as a member of the Kikuyu tribe at the age of thirteen. Louis later completed studies at Cambridge University in the fields of anthropology and archaeology. Louis and his wife Mary were both instrumental in shaping the fields of archaeology, paleoanthropology, and primatology due to their many discoveries.

Young Richard was often in the field with his parents on digs, and found his first fossil, of an ancient pig, at the age of six. During his youth, he had a horrible time with bullying in school and eventually left school to pursue his interest in observing and tracking animals. He initially resisted the idea of following the career path of his parents and decided to start a safari business. His business was fairly successful until his curiosity about paleontology led him in a different direction. Leakey began to go on fossil hunting expeditions in East Africa with colleagues of his parents. In 1967 he became part of an expedition funded through one of his father’s research projects: Richard served as the field leader for a trip to the Lower Omo Valley in Ethiopia. In this area, the team found many early hominid fossils that were at least 130,000 years old.

Around this time, Leakey married Margaret Cropper, who traveled with him on the Omo Valley expedition. He faced difficulty early in his career because he lacked the credentials that many anthropologists and archaeologists possessed. Thus, he returned to school and completed the requirements to gain entry into a university. After he completed his entrance exam, he aimed to pursue higher education, but was soon distracted by his curiosity about a particular archaeological site and his desire to obtain a position with the National Museums of Kenya. He chose not to attend college.

Leakey’s interest in further excavating Kenya was inspired by a flight from Omo to Nairobi. The aerial view
provided him with a glimpse of what appeared to be fossil-bearing sedimentary rock. He determined that he would obtain funding to go back to that area and find fossils on Kenyan land. His excavations in the area around Kenya’s Lake Turkana would yield many significant finds and result in his distinguished career in the field of paleoanthropology. In 1968 he began the first of many excavations at this site. He also began to lobby for a position with the National Museums of Kenya. He was named administrative director of the museums in May of 1968 and remained in this position until 1989.

Leakey and his wife Margaret had one daughter named Anna, who was born in 1969, but they were divorced soon after this time. Richard then met and fell in love with Meave Epps, a zoologist who had recently completed her PhD at the University of North Wales. They married and had two children: Louise born in 1972, and Samira born in 1974. Leakey established a camp in Koobi, which became the site of one of his best-known discoveries, called skull 1470. This discovery helped him mend a long-standing rift with his father that was instigated by conflicts between Richard’s role as the director of the National Museum and his father’s center, which had been in existence for many years. Richard was able to show skull 1470 to his father just before Louis died on a trip to London in October 1972.

The discoveries by Leakey’s team of the *Homo habilis* skull in 1972 and the *Homo erectus* skull in 1975 were significant findings. Leakey’s health began to suffer thereafter due to kidney disease, and he had to receive a kidney from his brother Phillip in 1979. Leakey is most well-known for the discovery in 1984 of what would become known as Turkana Boy, a *Homo erectus* skeleton roughly 1.6 million years old. Two members of his team have been credited with working with him on this find: Alan Walker and Kamoya Kimeu. It is one of the most complete *Homo erectus* skeletons ever found, and it has brought Leakey and Kenya worldwide acclaim in the field of paleoanthropology.

Leakey resigned his post as director of the National Museums of Kenya amidst a wave of controversy in 1989. Leakey had been appointed director of the Kenya Wildlife Service by President Daniel Arap Moi. In this capacity, he spoke out against the rampant practice of elephant poaching and created many enemies because of the confrontational methods of his antipoaching campaign. In 1993 Leakey lost both of his legs in a suspicious plane crash, although within a few months he was walking again on artificial limbs.

Accusations of corruption and fraud led to his resignation from his post with the Kenya Wildlife Service in 1994. In 1995 Leakey created a political party, called Safina, which stood in opposition to the Kenyan African National Union. Leakey was subjected to a public beating and humiliation in the streets by opponents. His tense relationship with political leaders and poachers in the country was a primary cause of this attack. Leakey was reappointed to a position with the Kenya Wildlife Service in 1999, but resigned again in 2001. His daughter Louise completed a PhD in paleontology at the University of London and has followed in the footsteps of her parents. She and her mother, Meave, continue to lead annual expeditions to the Turkana Basin. Leakey remains active, lecturing and writing books on the preservation of wildlife and the environment. He has authored seven books related to his life and work, including *Origins Reconsidered* (1992) and *The Origin of Humankind* (1994).

LEARNED HELPLESSNESS

The term *learned helplessness* was coined by psychologists Martin Seligman and Steven Maier in 1967 to describe the behavior of dogs who, after experiencing inescapable electric shocks behaved as if they were helpless. As with many terms in psychology, *learned helplessness* is both descriptive and explanatory. Learned helplessness describes a constellation of maladaptive passive behaviors that animals (dogs, rats, cats, fish, mice, and humans) frequently exhibit following exposure to uncontrollable events. Learned helplessness is also a cognitive, expectancy-based explanation; after repeated, inescapable, aversive helplessness, animals *expect* to be helpless and do not attempt to change the situation—they have *learned* that their actions are ineffective.

Research on learned helplessness began in the 1960s at Richard L. Solomon’s (1918–1995) psychology lab at the University of Pennsylvania. Graduate students Russell
Leaf and J. Bruce Overmier had discovered that after Pavlovian conditioning with unavoidable mild shocks, the lab dogs were useless for any subsequent experiments that required learning how to avoid or escape shock. The majority of the dogs would sit and passively endure the aversive but otherwise physically harmless shock. This phenomenon piqued the interest of graduate students Maier and Seligman, who set out to show that the dogs had learned more than just Pavlovian conditioning. Maier and Seligman suggested that the dogs had learned that when shocked, nothing they did mattered—they had learned that they had no control over their environment. This explanation was unusually “cognitive” given the behaviorist climate of that era.

Most early research on learned helplessness used a three-group, two-phase, experimental design to make sure that uncontrollability was the cause of the helplessness. In the first phase, one group experienced controllable aversive stimuli; for example, they could learn to avoid a shock by jumping across a barrier into a safe area. A second, “no control” group also experienced the aversive stimuli, but had no means by which to escape it. To make sure that subsequent differences in helplessness were not due to differences in the rate or length of exposure to the uncontrollable stimuli, experimenters pair, or yoke, each “no control” animal with a “has control” animal. The “no control” animal only experiences the aversive stimuli when the “has control” animal does. Researchers call this a “yoked control group.” Animals in a third naive control group experience no aversive stimuli at all. In the second phase, the experimenters subject all three groups to aversive stimuli in a new controllable context; in other words, all have equal opportunity to escape.

In Seligman’s studies, usually about two-thirds of the “no-control” dogs display helpless behavior in the new situation. Six percent of the naive control group dogs also displayed helplessness, which Seligman suggests may have been due to prior traumatic experiences. Typically helpless animals show signs of stress, such as lethargy, dejection, and reduced appetite, dominance aggression, sexual appetite, and serotonin levels.

These studies demonstrated that for most animals, uncontrollable aversive experiences have devastating effects on subsequent learning, motivation, and emotion. Seligman reports that therapy for dogs with learned helplessness required dragging them into the safe area a number of times before they began to respond on their own. On a positive note, Seligman and colleagues also found that they could “immunize” dogs against learned helplessness by giving them several trials of escapable shock before exposing them to inescapable shock.

Donald Hiroto and Seligman (1974) subsequently extended this research paradigm to humans, using insoluble discrimination problems rather than shocks. It is important to note that in this transition from animals to humans, stimuli aversiveness was not the only parameter to change; the transition also included a shift from simple taskless stimuli to tasks such as unsolvable discrimination problems or puzzles. This shift has complicated the explanation of learning deficits following failure. Additionally, human susceptibility to learned helplessness varies considerably across individuals and situations. These differences correlate with a variety of characteristics: low mastery behavior, anxiety, depression, need for structure, and ego value of academic performance, to name a few. Nonetheless, the core features of the learned helplessness phenomenon remain: (1) following an uncontrollable situation, people exhibit a variety of learning, motivational, and emotional deficits, including increased vulnerability to depression and anxiety; (2) previous exposure to controllable aversive events immunizes people against learned helplessness; and (3) forced exposure to controllable contingencies reverses learned helplessness.

A significant portion of research on learned helplessness in humans has focused on its relationship with reactive depression. One of the earliest, and perhaps most fertile, explanations of learned helplessness as a cause of depression was Lyn Abramson, Seligman, and John Teasdale’s 1978 reformulation of learned helplessness theory using concepts from Bernard Weiner’s attribution theory. This reformulation recognizes that much of life is uncontrollable, yet not everyone is depressed by it. According to the reformulation of learned helplessness theory, whether depression results from helplessness situations depends on the attributions people make about the causes of the negative event. Depression is more likely if persons attribute negative events to internal causes (“it’s me”), stable causes (“it’s going to last forever”), or global causes (“it’s going to mess up everything I do”). This pessimistic style is evident in a student who attributes her poor math performance to “being a girl” (internal and stable) and assumes that failure in a specific math class will mean the end of her medical school dream (a global attribution). In contrast, a student who attributes failure on an exam to not studying is protected from depression because he or she has attributed it to an internal (“I didn’t study”), unstable (“I can study next time”), and specific (“failing on this test isn’t going to mess up my whole life”) cause. Each of these causal attributions has a different effect on subsequent behavior. Global attributions generalize helplessness across tasks and time, internal attributions imply a sense of failed responsibility, and stable attributions imply that it is not possible to change the parameters of the current situation.

A large body of research has found long-term individual differences in explanatory style and vulnerability to helplessness. Persons who have experienced a significant...
childhood loss (e.g., the death of a parent) or trauma (e.g., sexual or physical abuse) are more likely to develop pessimistic explanatory styles. Research has also found that parents and children have correlated explanatory styles, and messages from peers, teachers, media, and other community members have an impact on children's explanatory style. The repercussions of explanatory style is still being studied, for example, the effects of pessimistic explanatory style on negative health outcomes, occupational success, and the quality of social relationships.

The concept of learned helplessness has also been used extensively in educational and social psychology; for example, there is now an impressive body of research on individual differences in persistence following failure on evaluative and learning tasks. Some people's motivation is unaffected by experiencing failure; rather, they use failure as an additional source of information. Consequently, their performance quickly rebounds when given solvable problems. In contrast, “helpless” people appear to crumble under the experience of failure, or even just difficulty. They may regress to a lower skill level, exhibit negative affect, and conclude that they lack ability. Learned helplessness theory argues that helplessness following failure-feedback is the result of learning that responses and outcomes are noncontingent, which interferes with subsequent learning. Research in achievement motivation has found, however, that helplessness following failure can also be a strategic way to protect self-worth (e.g., “If I don't try, failing won't make me look bad”). Achievement motivation researchers call this an ego or performance goal.

A large and productive body of research has explored individual differences in resiliency and helplessness through the lens of achievement goals. Researchers have identified two major goal orientations: mastery or task goals and performance or ego goals. Mastery goals focus on intrinsic reasons for learning, which protects against learned helplessness. Performance goals focus on extrinsic reasons for learning—demonstrating one's ability and competing with others—which reduces vulnerability to learned helplessness. Recent research has extended these concepts by distinguishing between ego goals that focus on the display of skill (performance approach) and ego goals that focus on avoiding displays of incompetence (performance avoidance).

Finally, from an information-processing perspective, Grzegorz Sedek (1990) has described the phenomenon of learned helplessness as a state of cognitive exhaustion produced by nonproductive problem solving. This perspective reminds us that giving up is also an adaptive response because animal brains have finite energy resources. Helplessness behavior may be an adaptive avoidance of indiscriminant persistence. From this perspective, helplessness is not so much “learned” as it is “triggered.” There is little disagreement among researchers that helplessness as described by Seligman is a real and fascinating phenomenon; however, there is less consensus about its cause. Presently, separate bodies of research (learning theory, cognitive theory, cognitive behavioral therapy, achievement motivation, and information processing) support the existence of the helplessness phenomenon, but each gives a somewhat different explanation of its cause (i.e., helplessness as learned, helplessness as a cognitive interpretation of events, helplessness as a form of ego protection, and helplessness as an adaptive conservation of resources). Future research should intentionally compare these causes and the perhaps differential conditions under which they occur.

LEARY, TIMOTHY
1920–1996

Timothy Francis Leary was a psychologist, scientist, and philosopher who made substantive contributions to interpersonal theory and methodology and also gained notoriety for his endorsement of and research on hallucinogens. Born in Springfield, Massachusetts, on October 22, 1920, Leary was an only child raised by his mother’s family in a devout Irish Catholic household. His father, a successful dentist and prominent member of the community, left the family when Leary was thirteen years old. Initially expelled from the University of Alabama for spending a night in the women’s dormitory, he appealed the dismissal in 1945 and was awarded his bachelor’s degree in psychology while serving in the army during World War II (1939–1945).

Leary met his first wife, Marianne, in 1944 while serving as a psychometrician at Deshon General Hospital in Butler, Pennsylvania. A year later they were married in the same hospital before departing for the state of Washington, where Leary began work on his master’s degree. In 1946 Leary received his master of science degree under the supervision of renowned psychologist Lee Cronbach (1916–2001) at Washington State University. The title of his master’s thesis was “The Clinical Use of the Wechsler/Mental Ability Scale: Form B,” which he later retitled “The Dimensions of Intelligence.” Following the completion of his master’s degree, Leary entered the doctoral program in clinical psychology at the University of California, Berkeley. In 1950 he received his PhD in clinical psychology with the dissertation “The Social Dimensions of Personality: Group Process and Structure.”

Leary’s seminal monograph, The Interpersonal Diagnosis of Personality: A Functional Theory and Methodology for Personality Evaluation, was a direct product of his doctoral thesis. First published in 1957, Leary considered his monograph to be a methodological extension of the interpersonal theory of Harry Stack Sullivan (1892–1949). According to Leary, the emotional, interpersonal, and social life of individuals could be best understood as attempts to avoid anxiety. Leary’s monograph focuses on five levels of personality that include: (1) public communication, (2) conscious communication, (3) private communication or preconscious symbolization, (4) unexpressed or unconscious communication, and (5) the value or ego-ideal.

The majority of Leary’s monograph is devoted to the development of a two-dimensional circumplex model of personality, his most lasting contribution to clinical psychology. Developed by Leary in collaboration with several of his mentors at Berkeley, the circumplex model presents a methodology for measuring interpersonal behavior using a collection of simple and specific behavioral descriptors. Each behavior is situated along a continuum defined by two dimensions: dominance-submission and hostility-affiliation. Sixteen generic interpersonal themes are identified along the circumference of a circle where the two dimensions comprise the circle’s axes. The circumplex model can be utilized for a variety of purposes, including the assessment of the structure of personality, temporal variation in personality, and variability in personality due to situational context. Extensions and revisions of the Leary circumplex continue to be developed with the primary goal of better measuring and understanding the multifaceted and complex nature of interpersonal relationships.

After a brief tenure as assistant professor at Berkeley (1950–1955), Leary worked as director of the prestigious Kaiser Foundation in Oakland, California (1955–1958), where he applied his circumplex model to understand the process of group psychotherapy. During the time of his greatest academic achievements, Leary experienced a personal tragedy when his wife committed suicide in 1955, leaving him to raise their eight-year-old daughter and six-year-old son.

In 1958 Leary left Berkeley with his two children and moved to Harvard, where he accepted a position as lecturer at Harvard’s Center for Personality Research and began the most controversial period of his academic career. In collaboration with his Harvard colleagues, most notably Richard Alpert and Ralph Metzner, Leary started an experimental research program examining the effects of psychedelic/hallucinogenic drugs on behavioral change. In a series of studies with Metzner, Leary explored the rehabilitative effects of psilocybin on young criminal offenders at the Massachusetts Correctional Facility in Concord. Leary believed that psilocybin, under guided professional supervision, could act as a conduit for internal reflection and behavioral change. In a second series of studies, Leary’s doctoral student, Walter Pahnke (1931–1971), examined the effects of psilocybin on the mystical and religious experiences of volunteer seminary students, hypothesizing that psychedelic drugs would facilitate such experiences.

Leary’s research, and his expulsion from Harvard in 1963, would catapult him into the public spotlight, where he became a counterculture icon. Popularizing the catch phrase “Turn on, Tune in, Drop Out” in the 1960s, Leary was an open advocate of the use of psychedelic drugs as a method of exploring and expanding consciousness. He
published several books on the subject, including *The Psychedelic Experience* (1964), coauthored with his former Harvard colleagues Metzner and Alpert. A controversial and outspoken figure throughout his life, Leary died of prostate cancer in 1996.

**LEAST SQUARES, ORDINARY**

Ordinary least squares (OLS) is a method for fitting lines or curves to observed data in situations where one variable (the response variable) is believed to be explained or caused by one or more other explanatory variables. OLS is most commonly used to estimate the parameters of linear regression models of the form

$$Y_i = \beta_1 + \beta_2 g_2(Z_{i2}) + \cdots + \beta_K g_K(Z_{ik}) + \varepsilon_i. \quad (1)$$

The subscripts $i$ index observations; $\varepsilon_i$ is a random variable with zero expected value (i.e., $E(\varepsilon_i) = 0$, for all observations $i = 1, \ldots, n$); and the functions $g_1(), \ldots, g_K()$ are known. The right-hand side explanatory variables $Z_{i2}, \ldots, Z_{ik}$ are assumed to be exogenous and to cause the dependent, endogenous left-hand side response variable $Y_i$. The $\beta_1, \ldots, \beta_K$ are unknown parameters, and hence must be estimated. Setting $X_j = g_j(Z_j)$ for all $j = 1, \ldots, K$ and $i = 1, \ldots, n$, the model in (1) can be written as

$$Y_i = \beta_1 + \beta_2 X_{i2} + \cdots + \beta_K X_{ik} + \varepsilon_i. \quad (2)$$

The random error term $\varepsilon_i$ represents statistical noise due to measurement error in the dependent variable, unexplained variation due to random variation, or perhaps the omission of some explanatory variables from the model.

In the context of OLS estimation, an important feature of the models in (1) and (2) is that they are linear in parameters. Since the functions $g()$ are known, it does not matter whether these functions are linear or nonlinear. Given $n$ observations on the variables $Y_i$ and $X_p$, the OLS method involves fitting a line (in the case where $K = 2$), a plane (for $K = 3$), or a hyperplane (when $K > 3$) to the data that describes the average, expected value of the response variable for given values of the explanatory variables. With OLS, this is done using a particular criterion as shown below, although other methods use different criteria.

An estimator is a random variable whose realizations are regarded as estimates of some parameter of interest. Replacing the unknown parameters $\beta_1, \ldots, \beta_K$ and errors $\varepsilon_i$ in (2) with estimators $\hat{\beta}_1, \ldots, \hat{\beta}_K$ and $\hat{\varepsilon}_i$ yields

$$Y_i = \hat{\beta}_1 + \hat{\beta}_2 X_{i2} + \cdots + \hat{\beta}_K X_{ik} + \hat{\varepsilon}_i. \quad (3)$$

The relation in (2) is called the population regression function, whereas the relation in (3) is called the sample regression function. The population regression function describes the unobserved, true relationship between the explanatory variables and the response variable that is to be estimated. The sample regression function is an estimator of the population regression function.

Rearranging terms in (3), the residual $\hat{\varepsilon}_i$ can be expressed as

$$\hat{\varepsilon}_i = Y_i - \hat{\beta}_1 - \hat{\beta}_2 X_{i2} - \cdots - \hat{\beta}_K X_{ik}. \quad (4)$$

The OLS estimators $\hat{\beta}_1, \ldots, \hat{\beta}_K$ of the parameters $\beta_1, \ldots, \beta_K$ in (2) are obtained by minimizing the error sum-of-squares

$$\text{ESS} = \sum_{i=1}^{n} \hat{\varepsilon}_i^2 = \sum_{i=1}^{n} [Y_i - \hat{\beta}_1 - \hat{\beta}_2 X_{i2} - \cdots - \hat{\beta}_K X_{ik}]^2 \quad (5)$$

with respect to $\hat{\beta}_1, \ldots, \hat{\beta}_K$. Hence the OLS estimator of the population regression function (2) minimizes the sum of squared residuals, which are the squared distances (in the direction of the $Y$-axis) between each observed value $Y_i$ and the sample regression function given by (3).

By minimizing the sum of squared residuals, disproportionate weight may be given to observations that are outliers—that is, those that are atypical and that lie apart from the majority of observations. An alternative approach is to minimize the sum

$$\sum_{i=1}^{n} |\hat{\varepsilon}_i|$$

of absolute deviations; the resulting estimator is called the least absolute deviations (LAD) estimator. Although this
least squares, ordinary

The estimator has some attractive properties, it requires linear programming methods for computation, and the estimator is biased in small samples.

To illustrate, first consider the simple case where \( K = 1 \). Then equation (2) becomes

\[
Y_i = \hat{\beta}_1 + \varepsilon_i
\]  

(6)

In this simple model, random variables \( Y_i \) are random deviations (to the left or to the right) away from the constant \( \beta_1 \). The error-sum-of-squares in (5) becomes

\[
\text{ESS} = \sum_{i=1}^{n} \varepsilon_i^2 = [Y_i - \hat{\beta}_1]^2.
\]  

(7)

This can be minimized by differentiating with respect to \( \beta_1 \) and setting the derivative equal to 0; that is,

\[
\frac{\partial \text{ESS}}{\partial \beta_1} = -2 \sum_{i=1}^{n} (Y_i - \hat{\beta}_1) = 0
\]

and then solving for \( \hat{\beta}_1 \) to obtain

\[
\hat{\beta}_1 = n^{-1} \sum_{i=1}^{n} Y_i.
\]

In this simple model, therefore, the OLS estimator of \( \beta_1 \) is merely the sample mean of the \( Y_i \). Given a set of \( n \) observations on \( Y_i \), these values can be used to compute an OLS estimate of \( \beta_1 \) by simply adding them and then dividing the sum by \( n \).

In the slightly more complicated case where \( K = 2 \), the population regression function (2) becomes

\[
Y_i = \beta_1 + \beta_2 X_{2i} + \varepsilon_i.
\]  

(8)

Minimizing the error sum of squares in this model yields OLS estimators

\[
\hat{\beta}_2 = \frac{1}{n} \sum_{i=1}^{n} (X_{1i} - \bar{X}_2) (Y_i - \bar{Y}) = \frac{1}{n} \sum_{i=1}^{n} (X_{1i} - \bar{X}_2)^2
\]  

(9)

and

\[
\hat{\beta}_1 = \bar{Y} - \hat{\beta}_2 \bar{X}_2
\]

where \( \bar{X}_2 \) and \( \bar{Y} \) are the sample means of \( X_{1i} \) and \( Y_i \), respectively.

In the more general case where \( K > 2 \), it is useful to think of the model in (2) as a system of equations, such as:

\[
Y_1 = \beta_1 + \beta_2 X_{12} + ... + \beta_K X_{1K} + \varepsilon_1
\]

\[
Y_2 = \beta_1 + \beta_2 X_{22} + ... + \beta_K X_{2K} + \varepsilon_2
\]

\vdots

\[
Y_n = \beta_1 + \beta_2 X_{n2} + ... + \beta_K X_{nK} + \varepsilon_n
\]

This can be written in matrix form as

\[
Y = X\beta + \varepsilon
\]  

(10)

where \( Y \) is an \((n \times 1)\) matrix containing elements \( Y_1, \ldots, Y_n \). \( X \) is an \((n \times K)\) matrix with \( X_{ij} \) in the \( i \)-th row, \( j \)-th column (elements in the first column of \( X \) are equal to 1); \( \beta \) is a \((K \times 1)\) matrix containing the unknown parameters \( \beta_1, \ldots, \beta_K \) and \( \varepsilon \) is an \((n \times 1)\) matrix containing the random variables \( \varepsilon_1, \ldots, \varepsilon_n \). Minimizing the error-sum-of-squares yields the OLS estimator

\[
\hat{\beta} = (X'X)^{-1}X'Y.
\]  

(11)

This is a \((K \times 1)\) matrix containing elements \( \hat{\beta}_1, \ldots, \hat{\beta}_K \). In modern software, \( \hat{\beta} \) is computed by inverting the \((K \times K)\) matrix \( XX \) using the \( Q-R \) decomposition. The OLS estimator can always be computed, unless \( XX \) is singular, which happens when there is an exact linear relationship among any of the columns of the matrix \( X \).

The Gauss-Markov theorem establishes that provided

i. the relationship between \( Y \) and \( X \) is linear as described by (10);

ii. the elements of \( X \) are fixed, nonstochastic, and there exists no exact linear relationship among the columns of \( X \); and

iii. \( E(\varepsilon) = 0 \) and \( E(\varepsilon\varepsilon') = \sigma^2 I \),

the OLS estimator \( \hat{\beta} \) is the best (in the sense of minimum variance) linear, unbiased estimator of \( \beta \). Modified versions of the OLS estimator (e.g., weighted least squares, feasible generalized least squares) can be used when data do not conform to the assumptions given above.

The variance-covariance matrix of the OLS estimator given in (11) is \( \sigma^2 (XX')^{-1} \), a \((K \times K)\) matrix whose diagonal elements give the variances of the \( K \) elements of the vector \( \hat{\beta} \), and whose off-diagonal elements give the corresponding covariances among the elements of \( \hat{\beta} \). This matrix can be estimated by replacing the unknown variance of \( \varepsilon \), namely \( \sigma^2 \), with the estimator \( \hat{\sigma}^2 = \hat{\varepsilon}\hat{\varepsilon}'/(n-K) \). The estimated variances and covariances can then be used for hypothesis testing.

**Discovery of the Method**

Robin L. Plackett (1972) and Stephen M. Stigler (1981) describe the debate that exists over who discovered the OLS method. The first publication to describe the method was Adrien Marie Legendre’s *Nouvelles méthodes pour la détermination des orbites des comètes* in 1806 (the term *least squares* comes from the French word *moindres carrés* in the title of an appendix to Legendre’s book), followed by publications by Robert Adrain (1808) and Carl Friedrich Gauss ([1809] 2004). However, Gauss made
several claims that he developed the method as early as 1794 or 1795; Stigler discusses evidence that supports these claims in his article “Gauss and the Invention of Least Squares” (1981).

Both Legendre and Gauss considered bivariate models such as the one given in (8), and they used OLS to predict the position of comets in their orbits about the sun using data from astronomical observations. Legendre’s approach was purely mathematical in the sense that he viewed the problem as one of solving for two unknowns in an overdetermined system of \( n \) equations. Gauss ([1809] 2004) was the first to give a probabilistic interpretation to the least squares method. Gauss reasoned that for a sequence \( Y_1, \ldots, Y_n \) of \( n \) independent random variables whose density functions satisfy certain conditions, if the sample mean

\[
\bar{Y}_n = n^{-1} \sum_{i=1}^{n} Y_i
\]

is the most probable combination for all values of the random variables and each \( n \geq 1 \), then for some \( \sigma^2 > 0 \), the density function of the random variables is given by the normal, or Gaussian, density function

\[
f(Y) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{1}{2} \frac{(Y - \mu)^2}{\sigma^2}\right).
\]

In the nineteenth century, this was known as the law of errors. This argument led Gauss to consider the regression equation as containing independent, normally distributed error terms.

The least squares method quickly gained widespread acceptance. At the beginning of the twentieth century, Karl Pearson remarked in his article in *Biometrika* (1902, p. 266) that “it is usually taken for granted that the right method for determining the constants is the method of least squares.” Beginning in the 1870s, the method was used in biological, genetic applications by Pearson, Francis Galton, George Udny Yule, and others. In his article “Regression towards Mediocrity in Hereditary Stature” (1886), Galton used the term regression to describe the tendency of the progeny of exceptional parents to be, on average, less exceptional than their parents, but today the term regression analysis has a rather different meaning.

Pearson provided substantial empirical support for Galton’s notion of biological regression by looking at hereditary data on the color of horses and dogs and their offspring and the heights of fathers and their sons. Pearson worked in terms of correlation coefficients, implicitly assuming that the response and explanatory variables were jointly normally distributed. In a series of papers (1896, 1900, 1902, 1903a, 1903b), Pearson formalized and extended notions of correlation and regression from the bivariate model to multivariate models. Pearson began by considering, for the bivariate model, bivariate distributions for the explanatory and response variables. In the case of the bivariate normal distribution, the conditional expectation of \( Y \) can be derived in terms of a linear expression involving \( X \), suggesting the model in (8). Similarly, by assuming that the response variable and several explanatory variables have a multivariate normal joint distribution, one can derive the expectation of the response variable, conditional on the explanatory variables, as a linear equation in the explanatory variables, suggesting the multivariate regression model in (2).

Pearson’s approach, involving joint distributions for the response and explanatory variables, led him to argue in later papers that researchers should in some situations consider nonsymmetric joint distributions for response and explanatory variables, which could lead to nonlinear expressions for the conditional expectation of the response variable. These arguments had little influence; Pearson could not offer tangible examples because the joint normal distribution was the only joint distribution to have been characterized at that time. Today, however, there are several examples of bivariate joint distributions that lead to nonlinear regression curves, including the bivariate exponential and bivariate logistic distributions. Aris Spanos describes such examples in his book *Probability Theory and Statistical Inference: Econometric Modeling with Observational Data* (1999, chapter 7). Ronald A. Fisher (1922, 1925) later formulated the regression problem closer to Gauss’s characterization by assuming that only the conditional distribution of the response variable is normal, without requiring that the joint distribution be normal.

**CURRENT USES**

Today, OLS and its variants are probably the most widely used statistical techniques. OLS is frequently used in the behavioral and social sciences as well as in biological and physical sciences. Even in situations where the relationship between dependent and explanatory variables is nonlinear, it is often possible to transform variables to arrive at a linear relationship. In other situations, assuming linearity may provide a reasonable approximation to nonlinear relationships over certain ranges of the data. The numerical difficulties faced by Gauss and Pearson in their day are now viewed as trivial given the increasing speed of modern computers. Computational problems are encountered, however, in problems with very large numbers of dimensions. Most of the problems that are encountered involve obtaining accurate solutions for the inverse matrix \((XX)^{-1}\) using computers with finite precision; care must be taken to ensure that solutions are not contaminated by round-off error. Åke Björck, in *Numerical Methods for

**LEAST SQUARES, THREE-STAGE**

The term *three-stage least squares* (3SLS) refers to a method of estimation that combines system equation, sometimes known as *seemingly unrelated regression* (SUR), with two-stage least squares estimation. It is a form of instrumental variables estimation that permits correlations of the unobserved disturbances across several equations, as well as restrictions among coefficients of different equations, and improves upon the efficiency of equation-by-equation estimation by taking into account such correlations across equations. Unlike the two-stage least squares (2SLS) approach for a system of equations, which would estimate the coefficients of each structural equation separately, the three-stage least squares estimates all coefficients simultaneously. It is assumed that each equation of the system is at least just-identified. Equations that are underidentified are disregarded in the 3SLS estimation.

Three-stage least squares originated in a paper by Arnold Zellner and Henri Theil (1962). In the classical specification, although the structural disturbances may be correlated across equations (*contemporaneous correlation*), it is assumed that within each structural equation the disturbances are both homoskedastic and serially uncorrelated. The classical specification thus implies that the disturbance covariance matrix within each equation is diagonal, whereas the entire system’s covariance matrix is nondiagonal.

The Zellner-Theil proposal for efficient estimation of this system is in three stages, wherein the first stage involves obtaining estimates of the residuals of the structural equations by two-stage least squares of all identified equations; the second stage involves computation of the optimal instrument, or weighting matrix, using the estimated residuals to construct the disturbance variance-covariance matrix; and the third stage is joint estimation of the system of equations using the optimal instrument. Although 3SLS is generally asymptotically more efficient than 2SLS, if even a single equation of the system is misspecified, 3SLS estimates of coefficients of all equations are generally inconsistent.

The Zellner-Theil 3SLS estimator for the coefficient of each equation is shown to be asymptotically at least as efficient as the corresponding 2SLS estimator of that equation. However, Zellner and Theil also discuss a number of interesting conditions under which 3SLS and 2SLS estimators are equivalent. First, if the structural disturbances have no mutual correlations across equations (the variance-covariance matrix of the system disturbances is diagonal), then 3SLS estimates are identical to the 2SLS estimates equation by equation. Second, if all equations in the system are just-identified, then 3SLS is also equivalent to 2SLS equation by equation. Third, if a subset of $m$
equations is overidentified while the remaining equations are just-identified, then 3SLS estimation of the $m$ overidentified equations is equivalent to 2SLS of these $m$ equations.

The 3SLS estimator has been extended to estimation of a nonlinear system of simultaneous equations by Takeshi Amemiya (1977) and Dale Jorgenson and Jean-Jacques Laffont (1975). An excellent discussion of 3SLS estimation, including a formal derivation of its analytical and asymptotic properties, and its comparison with full-information maximum likelihood (FIML), is given in Jerry Hausman (1983).

**LEAST SQUARES, TWO-STAGE**

Two-stage least squares (2SLS or TSLS) is an alternative to the usual linear regression technique (ordinary least squares, or OLS), used when the right-hand side variables in the regression are correlated with the error term. 2SLS uses additional information to compute asymptotically unbiased coefficients (i.e., approximately unbiased in large samples), in contrast to the OLS coefficients, which are biased even in large samples.

In the regression model with $k$ explanatory variables and $n$ observations

$$y = b_1x_1 + b_2x_2 + \cdots + b_kx_k + \varepsilon,$$

OLS will produce biased coefficients if any of the $x$ variables is correlated with the error $\varepsilon$. Such correlation may occur if any of the $x$ variables is measured with error, if relevant variables are left out of the specification, or if any $x$ variables are endogenous (determined in part by $y$).

Suppose the investigator has a list of $q$ ($q \geq k$) instrumental variables, $z_1, \ldots, z_q$, where to qualify as an instrument each $z$ must be correlated with one or more $x$ variables and must be uncorrelated with the error term. In the first-stage regressions, each $x$ is regressed on the instruments and the fitted value $\hat{x}$ is computed. By construction, $\hat{x}$ will be a proxy for $x$ that is uncorrelated with the error term $\varepsilon$. In this way, $\hat{x}$ is purged of the correlation that made $x$ unsuitable for use in the regression. In the second stage regression, $y$ is regressed on the set of fitted $\hat{x}$s. The estimated coefficients from this second stage are the two-stage least squares estimates of $b$. Appropriate adjustments are made to compute standard errors and other statistics associated with the regression, as the statistics reported directly in the second-stage regression are not valid.

In the simple case of one explanatory variable and one instrument, the formulas for the OLS and 2SLS coefficients are given by, respectively

$$\hat{b}_{2SLS} = \frac{\sum_{i=1}^{n} y_i x_i}{\sum_{i=1}^{n} x_i^2}, \quad \hat{b}_{OLS} = \frac{\sum_{i=1}^{n} y_i z_i}{\sum_{i=1}^{n} z_i x_i}.$$

Note that modern software computes 2SLS coefficients directly, rather than actually computing two stages of regression.

The difficult task in using 2SLS is to specify a list of instruments known a priori to be uncorrelated with the error term. In a linear simultaneous equation model, all exogenous variables (those variables not determined in the model) are candidates to serve as instruments. In particular, a variable may serve both as an explanatory variable and as an instrument ($x$ and $z$) if it is uncorrelated with the error. Identification requires that the number of instruments, $q$, be equal to or greater than the number of right-hand side variables, $k$.

2SLS is an instrumental variable (IV) estimator and the terms 2SLS and IV are often used interchangeably. Estimators closely related to 2SLS include the generalized method of moments (GMM) for nonlinear estimation, three-stage least squares (3SLS) for estimation of systems of equations, and limited-information maximum likelihood (LIML).
2SLS is a well-established technique, particularly in economics. Difficulties due to weak instruments, where the correlation between $x$ and $z$ is very low, constitute an ongoing area of investigation.

**LEBANESE CIVIL WAR**

The Lebanese civil war erupted in April 1975 and ended in October 1990. Since its independence in 1943, Lebanon has been governed by a confessional political system in which parliamentary seats and governmental and civil service positions are distributed among religious sects in accordance with their population ratio. The 1926 constitution, which officially recognizes the distribution of cabinet positions and governmental jobs on a sectarian basis, was supplemented at the time of independence in 1943 by an informal “gentlemen’s agreement,” the National Pact, at the time of independence. According to this agreement, the president has to be a Maronite Christian, the prime minister a Sunni Muslim, the speaker of the Parliament a Shia Muslim, and the deputy speaker a Greek Orthodox. The Muslims shunned pan-Arabism and recognized Lebanon's independence; Christians agreed to the Arab character of the country and eschewed western protection. This consociational democracy was based on cooperation and moderation among mainly Maronite and Sunni elites, perpetuated a weak state, and institutionalized the sectarian differences. Despite its defects, though, the Lebanese political system established order and stability from 1943 until 1975, weathering the crises of 1952 and 1958.

**CAUSES OF THE WAR**

Several developments in the 1960s undermined the precarious Lebanese republic. First, socioeconomic developments exacerbated economic inequalities. The Lebanese economy was characterized by free trade, low industrialization, low taxation, and minimal state intervention. Hence, the state was in position to effectively address the needs of the poorer segments of the population. Also, economic differences overlapped with sectarian differences: whereas Christians in general disproportionately benefited from the economic growth, the Shia remained at the bottom of the socioeconomic ladder. Second, demographic trends changed the population ratio between sects. The Shia had the highest fertility rate, followed by the Sunnis. The distribution of political power, which was based on the 1932 census, ceased to reflect demographic realities, and these developments augmented the Muslim demand for institutional reform. The rise of radical and populist forces undermined the power of the traditional Sunni and Shia elites. Third, and most importantly, regional events put immense burdens on the Lebanese political system. The rise of Arab nationalism in the 1950s exacerbated the sectarian tensions in Lebanon. Although Sunni Muslims were supportive of the anti-western policies of Egyptian president Gamal Abdel Nasser (1918–1970), the Maronites adamantly refused to allow Lebanon to join the pro-Nasser camp. Lebanon was on the brink of civil war in 1958 when the Maronite president asked for help from the United States. The landing of the U.S. marines in Beirut quelled the violence, and a compromise candidate, Fuad Chehab, was elected president. After the 1967 Six Days War and their expulsion from Jordan in 1970, Palestinian guerillas chose Lebanon as the main base of their operations against Israel. The November 1969 Cairo agreement between Lebanon and the Palestinian Liberation Organization (PLO) gave the PLO extraterritorial rights. The entrenchment of the PLO in Lebanon provoked Christian resentment because it further changed the demographic ratio to the disadvantage of Christians, and it brought fierce reprisals from the Israelis, who held the Lebanese government responsible for the actions of the Palestinians. The Lebanese army was unable to control the PLO or to defend the country against Israeli incursions. The insecurity in southern Lebanon led to the dislocation of Shia villagers to urban peripheries. Furthermore, after Hafez al-Assad (1930–2000) assumed the presidency of Syria in 1970, Syria pursued a more assertive and ambitious foreign policy in Lebanon. The ruling Alawite minority perceived the Shia of Lebanon as a counterweight against the Sunni majority of Syria and the Palestinians.

By 1975 two main coalitions were confronting each other. On the one hand, Maronite Christians came together under the rubric of the Lebanese Forces (LF), which was dominated by the Phalange Party led by Bashir Gemayel (1947–1982). The LF was in favor of the continuation of the existing confessional system of government in Lebanon and opposed any institutional reform benefiting the Muslims. Moreover, it espoused the end of Palestinian extraterritorial rights. During the conflict, the LF toyed with the idea of creating a small Christian state in Mount Lebanon, an idea that was rejected by several more moderate Maronite leaders. On the other hand was
an amalgam of groups that demanded the end of the confessional system and sympathized with the Palestinian goals. The Lebanese National Movement (LNM) included the Progressive Socialist Party (PSP) led by the Druze leader Kamal Jumblatt (1917–1977), the Amal militia headed by the Shia leader Musa al-Sadr (1928–1978), the Syrian Social Nationalist Party (SSNP), the Communists, the Arab nationalist Ba’th Party, and the Sunni al-Murabitun militia, and it had the support of the PLO.

**FIGHTING FROM 1975 TO 1985**

Fighting broke out between Palestinian guerrillas and the Phalange in April 1975, and several months later Lebanon was engulfed in full-scale civil war. The first phase of the civil war continued for eighteen months. By December 1975 the LNM was on the verge of defeating the LF, but Syria intervened to prevent that outcome because the ruling Alawite regime in Syria feared that the dissolution of Lebanon or the leftist and PLO domination of Lebanon would jeopardize its rule over the Sunni majority in Syria. Both the United States and Israel gave tacit agreement to Syria’s intervention, which resulted in de facto partition of Lebanon. With the Syrian army in control of most of the country, the LF, the PLO, the Druze, and the pro-Israeli Free Lebanon Army established themselves in different parts of the country. The United Nations Interim Force in Lebanon (UNIFIL) became a buffer between the pro-Israeli militia and the PLO.

From 1976 to 1982 the conflict between the PLO and Israel continued unabated. In March 1977 Jumblatt was assassinated, and the LNM was beset by factionalism. In August 1978 al-Sadr disappeared while on a trip to Libya. Meanwhile, the relations between the LF and Syria deteriorated, and the Syrian regime suppressed the Muslim Brotherhood after much bloodshed. In 1981 Syrian-Israel relations deteriorated further, and Israel initiated a large-scale invasion of Lebanon in 1982. The Israeli goals were the destruction of PLO autonomy, the weakening of the Syrian influence in Lebanon, and most ambitiously, the reconstruction of the Lebanese state under the control of Gemayel, who allied himself with the Israelis. The invasion achieved its first goal, as the PLO was obliged to leave West Beirut in 1982 and later, Tripoli in 1983 after the Syrian attacks. However, the Israeli army’s defeat of the Syrian forces did not end Syrian influence, which was rapidly restored with Soviet support. Gemayel was assassinated in September 1982, shortly after he was elected president. A security pact signed between Israel and Lebanon in May 1983 was later abrogated. Moreover, the LF massacres of Palestinian refugees in the Sabra and Shatila camps surrounded by the Israeli army in September 1982 left the Israeli goal of establish-

**END OF THE CIVIL WAR**

The later 1980s saw intra-sectarian conflict among the Muslims and Christians and the complete fragmentation of the state authority in Lebanon. The Shia militia Amal took over West Beirut in February 1984, and tensions between Amal and the Palestinians erupted into open conflict—the “war of the camps”—in 1985, prompting the Syrian occupation of West Beirut in 1987. Armed rivalry between Hezbollah and Amal from 1988 to 1990 resulted in the establishment of the former as a major force in Beirut. Among Christians, General Michel Aoun (b. 1935), the commander of the Lebanese army, emerged as a strong contender for leadership; President Amine Gemayel appointed him prime minister in 1988 in defiance of the National Pact. Aoun vehemently opposed Syrian interference and portrayed himself as a secular nationalist leader. He clashed with the LF for control of the Christian enclave and declared a “war of liberation” against Syria in March 1989. He was ultimately unsuccessful, and was forced into exile in 1991. With his defeat, the Lebanese Civil War came to an end.

A principal reason for the end of active hostilities was the exhaustion brought on by the fifteen years of warfare. None of the groups was able to establish dominance over others, and sectarian divisions continued as before. Syria emerged as the hegemonic power in Lebanon, with U.S. endorsement, and achieved veto power over all important political decisions. The Ta’if Agreement (1989), which was signed by the surviving Lebanese parliamentarians and crystallized the ethos of “no victor and no vanquished,” amended the constitution but did not dismantle confessionalism. By its terms, the power of the president was reduced in favor of the prime minister and the speaker of the Parliament, and the parliamentary seats were equally distributed between Christians and Muslims. All the militias were disarmed in March 1991 with the exception of Hezbollah, which continued its “resistance”
against Israel in the border zone. Syria did not completely withdraw from Lebanon until 2005.

LE DUC THO
1911–1990
Phan Dinh Khai was born the son of a midlevel Vietnamese civil servant in Nam Ha Province of French Indochina on October 14, 1911. He changed his name to Le Duc Tho when he became a committed revolutionary during his teenage years. In 1929 Tho joined with Ho Chi Minh (1890–1969) and other Vietnamese radicals in founding the Indochinese (later Vietnamese) Communist Party. For agitating against French rule, Tho and his comrades spent much of the 1930s in French colonial prisons. During World War II (1939–1945), Tho helped to organize the Viet Minh, the Communist-led resistance movement against the Japanese occupiers of Indochina. By the end of the war, Tho was a member of the Central Committee of the Communist Party and a leader of the Viet Minh. When France tried to retake Indochina in 1945, Tho led southern Viet Minh resistance during the Indochina War (1946–1954). With the defeat of the French, North Vietnam gained independence. Tho became a member of the Politburo in 1955 and secretary of the Central Committee in 1960.

For their role in ending the American phase of the Vietnam War, Tho and Kissinger were jointly awarded the 1973 Nobel Peace Prize. Tho was the first Asian ever to win this honor—but he declined the award, saying that peace had not yet come to his country. Instead, Tho returned to South Vietnam to supervise the North Vietnamese offensive that delivered a Communist victory in 1975. A decade later, Tho told U.S. television viewers: “We hope American wives and mothers will never again allow their husbands and sons to go to die in another Vietnam War anywhere in the world” (quoted in Dowd 1985, p. A4). Tho remained active in party leadership after the war and oversaw the Vietnamese invasion of Cambodia in 1978, but he opposed economic reforms introduced by his government in the 1980s. Out of step with changes in Vietnamese Communism, Tho resigned his official posts in 1986 and retired. He died of cancer on October 13, 1990.

LEE, ROBERT E.
1807–1870

Robert Edward Lee was the most famous general of the Confederate forces during the American Civil War (1861–1865). Lee served as commander of the Army of Northern Virginia and eventually general-in-chief of the entire Confederate Army until the war’s completion in 1865.

Lee was born January 19, 1807, in Westmoreland County, Virginia. His father, whom he barely knew, was the famous Revolutionary War hero, Henry “Light Horse Harry” Lee (1756–1818). In 1829 Robert E. Lee graduated second in his class without a single demerit at the United States Military Academy in West Point, New York. In 1831 Lee married Mary Custis (1808–1873), a great-granddaughter of Martha Washington (1731–1802). Together they had seven children.

During the Mexican War (1846–1848), Lee served on the staff of General Winfield Scott (1786–1866). As an engineer, Lee directed the placement and transport of heavy artillery in the Veracruz landing and subsequent march to Mexico City in 1847. In 1852 he became superintendent of West Point. In 1859 he commanded a force of marines that together with local militia put down John Brown's (1800–1859) raid of the Harpers Ferry armory.

Lee headed the Department of Texas from 1860 until March 1861. In April, in Washington, D.C., he was offered and then declined the command of the Union (North) Army. Within the month, he had joined the Confederate Army. In 1862 he assumed command of the Army of Northern Virginia, leading Confederate forces to decisive victories at such battles as Second Bull Run (August 1862), Fredericksburg (December 1862), and Chancellorsville (May 1863). He and his army suffered a crushing defeat at the Battle of Gettysburg in July 1863, arguably the turning point of the American Civil War. Shortly after the defeat at Petersburg, Lee surrendered the Confederate forces to Union general Ulysses S. Grant (1822–1885) on April 9, 1865, at Appomattox Courthouse in rural Virginia.

Following the war, Lee served as president of Washington College (later renamed Washington and Lee College) in Lexington, Virginia. He died of pneumonia on October 12, 1870, and was buried underneath the chapel at Washington College.

TRADITIONALIST AND REVISIONIST HISTORY ON LEE

Much of the literature on Robert E. Lee can be categorized by two historical perspectives. The traditionalist perspective interprets Lee as noble and full of virtue, fighting for the South out of a sense of duty to protect his Virginia homeland and confronted by forces beyond his control that compelled him to serve and fight against the Union. This perspective originated in the 1870s, was reinforced and consolidated over the following decades, and culminated with the publication of Douglas Freeman’s four-volume biography, *Lee* (1934). In contrast, Thomas Connelly’s *Marble Man* (1977) exemplifies the revisionist perspective, which took a more critical view of Lee as a southerner and as a soldier.

Proponents of these perspectives contest much about Lee’s life, but three debates remain especially salient. The first surrounds Lee’s views on slavery (Fellman 2000, esp. chap. 4). Traditionalists resurrected a Lee that was anti-slavery, and fought for the Confederacy despite this. They cite as evidence Lee’s letters where he referred to slavery as a “moral and political evil” and that Lee manumitted slaves held by his father-in-law, George Washington Parke Custis (1781–1857), after the latter’s death. Nevertheless, this did not mean Lee supported abolition; although Lee spoke of slavery as a moral and political evil, in the same correspondence he also claimed that slavery was God’s will, that “blacks are immeasurably better off here [enslaved] than in Africa … the painful discipline they are undergoing, is necessary for their instruction as a race…. Their emancipation will sooner result from the mild and melting influence of Christianity, than the storms and tempests of fiery Controversy” (Freeman 1934, p. 372).

The second debate focuses on Lee’s responsibility for the Confederate defeat at the crucial Battle of Gettysburg in 1863. Many traditionalists, such as Confederate general Jubal Early (1816–1894), generally blamed General James Longstreet (1821–1904) for his slow execution of Lee’s plan to attack Union forces at Cemetery Ridge on July 2, 1863. Revisionist critics, including historical novelist Michael Shaara, author of *The Killer Angels* (1974), attribute the Confederate loss to Lee’s poor judgment in attacking a Union force that possessed superior ground and material and a greater quantity of troops.

A third debate centers on Lee’s involvement with the secessionist movement and his subsequent decision to serve in the Confederate forces in 1861. Proponents of both perspectives agree on two facts regarding this issue: (1) that Lee viewed secession as illegal, and (2) that he was offered, and declined, the position of commander of Union forces by the U.S. government. Traditionalists argue that Lee tortured over the decision to fight for the Confederacy, ultimately deciding to fight out of a sense of
“duty” to Virginia: “If secession destroyed the Union, Lee intended to resign from the army and to fight neither for the South nor for the North, unless he had to act one way or the other in defense of Virginia” (Freeman 1934, p. 423). Revisionist Connelly, while conceding that Lee equated secession as “nothing but revolution,” questions the traditionalist interpretation, asking: “One wonders why Lee did not endeavor to use his influence within Virginia to squelch the secession movement? He certainly might have been able to do it” (1977 p. 198). In addition, “almost instantaneously the secession movement which he supposedly abhorred was a holy cause, and the Union he loved had become a deadly enemy” (p. 201). In contrast with the “tragic hero” of Freeman’s Lee, Connelly’s is “a child of the seventeenth-century New England mind, and not of the later Enlightenment,” one whose “belief implied an unquestioning spirit which submitted to unseen forces … and a denial of the reasoning process” (p. 199). Yet no evidence exists that Lee was active in the secessionist movement. His service in Texas immediately prior to Virginia’s secession makes it difficult to suggest that Lee was a secessionist conspirator.

Scholars and students of history and the social sciences should take special note of Robert E. Lee as a model of historiography—an example of how interpretations of the past may serve the interests of those living in the present.

Lefebvre, Henri
1901–1991

Known as the “father of the dialectic,” Henri Lefebvre was a key figure in the dissemination of the theory and method of dialectical materialism outside of Communist countries in the twentieth century, thanks to his widely translated Le matérialisme dialectique (Dialectical Materialism, 1939) and other works that emphasized a philosophically rigorous approach to the work of Karl Marx (1818–1883), G. W. F. Hegel (1770–1831), and Friedrich Nietzsche (1844–1900). One of the first serious French commentators on these scholars, Lefebvre pioneered their translation and popularization. He advocated the application of dialectical materialism as a methodology, even when it challenged Marxist orthodoxy. Lefebvre encouraged the elaboration of social critique by later generations, including the Situationniste Internationale group, 1960s student activists, 1970s Marxist critics of urban governance, and the 1980s critical postmodernists in the United States. Lefebvre was a witness to both world wars and to the modernization of everyday life in France, including the industrialization of the rural economy and the suburbanization of its cities.

In the early 1950s, Lefebvre was the measure of orthodoxy for pre-Stalinist French Marxism, until his humanism and interest in the alienated quality of everyday life led to expulsion from the Parti Communiste Français. These themes can be found in his series of works on the banality (quotidiennité) of everyday life under capitalism, Critique de la vie quotidienne (Critique of Everyday Life, 4 vols., 1958–1981), in which he examines such topics as the requirement to commute long distances and work long hours. Reacting against his youthful romanticism and Martin Heidegger’s (1889–1976) metaphysical critique of Alltäglichkeit (everydayness, banality), rather than seek an aesthetic or poetic solution to the problem of alienation, Lefebvre argued for concrete changes in collective practice. Contemporary social life is not just banal, it is the deliberate outcome of a bureaucratized, consumption-oriented society, suggesting that changes in its organization are required, not more refined individual sensibilities.

The commercialized and inauthentic ambient environment in cities, suburban developments, and housing design inspired his critiques of contemporary planning practice and the development of a critical theory of the production of these environments as social spaces. In collaboration with members of the Situationniste Internationale, whom he met in Strasbourg while establishing one of the first sociology departments in France, he championed the revolutionary potential of the ludic and the carnivalesque. This perspective informed the strategy of Lefebvre’s later students in May 1968 at the University of Nanterre when they initiated student unrest in Paris. The inconclusive outcome was seen at the time as a failure of Lefebvre’s Marxist humanism. However, interest in his pioneering appreciations of the spatial matrix and rhythms of urban life resumed in the 1990s.

Brent J. Steele
Lefebvre was widely influential as a critic of structuralism, a founder of rural sociology, and an analyst of the role of the state in the creation of favorable conditions for capitalists and for the organization of production. He stressed that this took material and performative, rather than ideological forms. Capitalism is embodied, it is a built environment and landscape, and it is lived in the rhythms and divisions of our days.

LEFT AND RIGHT
*Left and Right* are benchmarks of spatial understandings of politics. Such descriptions are widely used as shorthand for communicating information about relative policy positions. The origin of the terms, designating positions of factions in the French revolutionary assembly, reflects a transformation from a vertical, or hierarchical, understanding of politics to a horizontal, or democratic, arrangement of conflict. Thus, the spatial metaphor is not just useful; it is fundamental to the way that people decipher democracy.

The terms should be used with care, however. There is some consistency in the meaning of *left* and *right* for political position across time and space. But the particular associations between left and right and definite policy positions are inexact and changeable. And many issues and perspectives correspond only loosely, at best, to a position on a stylized left-right dimension.

ORIGINS
The first use of the left-right spatial metaphor was in France, in the period following the Revolution of 1789. Before the revolution, the polity had been divided into caste-like "estates." The first estate was the clergy; the second was the hereditary nobility. The third estate (artisans and professionals) was more numerous but politically weaker.

French society was explicitly hierarchical, with the monarch being superior to all estates. “Position” was defined by class and station, which were in turn decided at birth. The idea of political positions as ideative views of the good, rather than simply shared interests of the estate or class one belonged to, had little place in such a system.

But the French Revolution, literally and figuratively, leveled many of the institutions of France. Historians Alexis de Tocqueville and Francois Guizot, separately looking back decades later at the impact of the French Revolution, both used the word “leveling” to describe its primary political impact. But this meant that two traditional links had been broken. First, the inherent connection between a fixed caste and its place in society was uprooted. Second, all citizens took an equal place in the society, each equally worthy of respect and equally politically powerful.

With the passing of the static caste-based conception of French society, citizens sought some effective way of mentally organizing the new, often chaotic, situation. What was required was a mental construction based on politics (the contest among equals, on a level playing field), not class or estate (immutable vertical distinctions of social privilege and political advantage). The replacing of the vertical understanding of hierarchy with the spatial metaphor of political disputes among equals may have been inevitable. Spatial imagery was the result of the new vision citizens in a democracy had of the alternatives open to them.

The French National Convention, meeting in September 1792 in the aftermath of the dissolution of the Legislative Assembly, was chaotic and unruly. A significant plurality of the deputies elected to the convention was independent. They were too poorly organized to raise issues on their own, but at more than 500 they were numerous enough to determine the outcome on most votes. They were seated in the middle section of the huge hall, an area referred to as "the Plain."

The Gironde, the party physically located on the right of the hall (in the convention as had been true in the two previous assemblies), controlled the government in this period. They were pro-business, and advocated only mild and marginal reform of institutions. Their power base lay in the relatively conservative provinces.

The denizens of “the mountain,” the high benches on the far left of the assembly hall, were the most organized opposition to the Girondins. These overtly populist Jacobins agitated for change, for radical reform, and for anything else that made it more difficult for the Gironde to control the country. Their focus was on centralization of power in Paris, reform of banks and the monetary system, and widespread nationalization of the assets and wealth of the first two estates.

The Gironde, the party on the right, proved unable to pursue its mix of military defense, free trade economi-
ics, and fiscal restraint. By the spring of 1793, the government collapsed. The Jacobins, the party seated on the left of the hall, seized its opportunity to implement a variety of collectivist reforms and political purges. These general associations, with the party of the right defending the status quo and the party of the left attempting to implement reforms and significant changes, persists in our political language still.

GENERAL CATEGORIES OF MEANINGS OF LEFT AND RIGHT
Spatial descriptions of positions have become nearly generic, like using “Coke” as a name for any carbonated cola drink. But it is a mistake to think that such generic designations have more than colloquial meaning in any specific political situation. Further, the generic meanings themselves are contradictory, or at least fundamentally different.

Keeping this caveat in mind, there are at least three broad categories of meaning for the labels Left and Right.

1. Divisions with respect to perspective on property. Left: Public ownership of the means of the production, government uses its power to redistribute wealth and power to achieve near-equality. Right: Private ownership, capitalist economy, government uses its power to preserve deep disparities in wealth and social status.

2. Divisions with respect to status quo policy of current government. Left: Radical reformers, seek to change status quo policies and break free from outmoded repressive rules of the past. Right: Conservative defenders of the status quo, tradition, and customary relations.

3. Fairness-based divisions. Left: Emphasize fairness in terms of outcomes. In different ways, this perspective is embodied in such thinkers as Jean-Jacques Rousseau, Karl Marx, or John Rawls. Right: Emphasize fairness in terms of process, and stability of use of traditional processes. Examples include Robert Nozick’s focus on historical principles, or Edmund Burke’s defense of tradition and custom.

PROBLEMS: TIME, CULTURAL UNDERSTANDING, AND STRATEGIC ACTION
The use of the left-right spatial metaphor makes several hidden assumptions that are arguable, at best. First, there is a single primary dimension of political and social conflict in the society. Second, this dimension and its connection to specific issues and beliefs are constant over time. Third, this dimension of conflict is transcultural, implying that the same understanding of left-right imagery and its connection to everyday politics is broadly shared.

It is more likely that, though the use of left-right as a means of organizing discourse about politics is generally useful, the actual meaning of the end points, or extremes, of Left and Right are both time-bound and culturally specific.

LEFT WING
The term left wing originated with the seating arrangement of the French National Assembly of 1791. The deputies representing the Third Estate, the ordinary people, were seated to the left of the president’s chair on an elevated section called the Mountain, while the nobility, the Second Estate, sat on the right side of the chamber. Between them sat a mass of deputies, known as the Plain, who did not belong to any particular faction.

CHANGING MEANINGS
Originally most members of the French National Assembly seated on the left were moderate reformers who called for a constitutional monarchy and a unicameral legislature for France. On the right sat the delegates who supported the more conservative royalist, aristocratic, and clerical interests. But the Left/Right labels took on new meanings during the course of the French Revolution, which began in 1789. The Left became increasingly radicalized as Maximilien Robespierre (1758–1794), Louis Saint-Just (1764–1794), Jean-Paul Marat (1743–1793), and the powerful Jacobin clubs (the most famous political group of the French Revolution) gained influence. Under their sway, King Louis XVI (1754–1793) was executed, a republic was declared in France, and the Reign of Terror (the period of the French Revolution when thousands of people were executed) commenced. Anyone who opposed the monarchy, or ancien régime (old order), was regarded as a member of the Left. Although differing on the polit-
ical objectives, the Left and the Right shared similar economic views. Both factions supported laissez-faire capitalism and free markets, ideas later espoused solely by the right wing. Some radicals on the far Left, though, held that the revolution’s promise of equality could only be achieved by redistributing wealth and land. Recognizing that genuine equality could not be fully realized without government intervention on behalf of the poor, the Left in European politics generally came to embrace socialism.

LEFT-RIGHT POLITICAL SPECTRUM
Political scientists and historians typically use the Left-Right political spectrum to classify modern political ideologies. At the extreme left end of the Left-Right divide are the communists and revolutionary socialist groups, such as the syndicalists, who historically endorsed the use of armed rebellion for achieving power and totalitarian means for imposing their socialist schemes. Moving toward the left-center of the spectrum are the social democrats, Christian socialists, Fabian socialists, Proudhonists, evolutionary socialists, and various groups associated with trade union movements. These groups believe that socialism can be established through democratic and incremental methods. At the opposite side of the political spectrum are such groups as the fascists, who believe in a centralized autocratic government often headed by a dictatorial leader. The far Right typically favors a corporatist economy and the mobilization of the nation against Marxist internationalism. Often these ideologies were espoused by military dictatorships, such as that of Juan Perón (1895–1974) of Argentina. On the right-center are the royalists or monarchists, followed by other traditional conservatives, such as British politician and orator Edmund Burke (1729–1797). Anarchists and libertarians were and are difficult to position on the Right-Left political continuum, since there are left-wing and right-wing variants of each.

What it means to be a left-winger varies depending on the country, culture, and particular issue. Since the eighteenth century until the latter part of the twentieth century, right- and left-wing ideologies battled mostly over questions of economics and class. The Left sought to equalize wealth and property while the Right defended the property interests of the privileged classes. Left-wingers always saw themselves as defenders of the disadvantaged and oppressed against the privileged elite. For them the equality of humankind was both a biological given and a political goal. The afflictions from which people have historically suffered, such as poverty, war, strife, crime, and so on, would be eradicated, they held, as advances toward greater economic, social, racial, and gender equality were made. The Left generally opposed at least in principle the institutionalization of sexual distinctions. Since the natural equality of people is assumed, they blamed the persistence of social and economic inequalities on the maldistribution of wealth and property which fosters in turn the social prejudices that perpetuate and entrench the class system. Left-wingers tended to be social and economic levelers who believed that human nature itself can be transformed and improved through governmental action. People are born good, they held, but their natural goodness is corrupted by the environment. Hence leftists had an enormous faith in the efficacy of their political schemes to perfect human nature. Most social problems, it followed, could be remedied by economic fixes or social engineering. To achieve these ends, left-wing movements advocated central economic planning and nationalization of the economy. They were and are generally hostile to intermediary groups and associations such as local governing authorities, religious institutions, civic organizations, privately owned businesses, and traditional family structures that impede the power of the central government to reconstruct society in a more egalitarian direction.

During the French Revolution the Jacobins violently attacked the Roman Catholic Church and attempted to replace Christianity with the worship of “Reason.” Left-wing ideologies continue today to be generally secular. The separation of church and state is a basic principle to the Left. Some believe that all religious expression should either be strictly limited or suppressed, while more religiously tolerant leftists would argue only that religion should play no part in political discourse.

THE LEFT WING IN THE TWENTY-FIRST CENTURY
Beginning in the latter part of twentieth century, moral, cultural, and social issues, such as abortion, gay rights, secularism, feminism, and multiculturalism, rather than economic or class questions, have come to characterize Left-Right political struggles. The Left typically today supports the legalization of gay marriage, extending abortion rights, and opening the national borders to unrestricted immigration. Opponents of these policies are sometimes accused of being hatemongers, homophobes, male chauvinists, and racists. These cultural wars have almost totally replaced the economic class warfare that once dominated Western politics. The central creed of the post-Marxist Left, as historian Paul Gottfried (1943–) argued in his The Strange Death of Marxism: The European Left in the New Millennium (2005), is no longer the elimination of economic classes but the establishment of the therapeutic-managerial state in which all gender, ethnic, racial, and cultural distinctions have been abolished.

The Left in the early twenty-first century would include the European Social Democrat and Green parties,
Legacy Effects

the Labour Party of Great Britain, the much weakened European Communist parties, and the liberal wing of the United States Democratic Party. Left-wing political movements are still strong and active on the South American and African continents. As self-proclaimed Marxist Peoples’ Democracies, the governments of Cuba and North Korea are leftists as well. American neoconservatism, some critics argue, should be considered a movement of the Left rather than the Right since it, like the French Jacobins, gives primacy to the principle of equality and supports global crusades to spread human rights and democracy.

The term left wing is rarely embraced by those who profess beliefs that would place them on the left end of the political spectrum. Rather the preferred label is progressive, which implies a commitment to egalitarianism and a willingness to promote governmental programs to help the poor, disadvantaged, and minorities. In the early 2000s the term was usually employed as a pejorative label by such right-wing political commentators as Rush Limbaugh, Bill O’Reilly, Ann Coulter, and Michelle Malkin, who applied it to their ideological adversaries.

LEGACY EFFECTS

Legacy effects are the impacts that one generation leave on the environment for future generations to inherit. There are very few parts of the globe where human beings have not left their imprint or legacy. Archeological evidence suggests that from the earliest times the human, the hunter, was responsible for the extermination of numerous other forms of life—flora and fauna—a pattern that persists today. The early civilizations changed watercourses, initiated farming, and denuded landscapes of many species of trees and shrubs; the barren lands of the eastern Mediterranean, for example, are largely a legacy of the classical period of ancient Greece. The advent of industrialization and mass production has resulted not only in further damage to the natural landscape as massive resource depletions take place, but also legacies of unsightly built environments.

Legacy effects are not all negative, at least in terms of public perception. Although the classical period saw the destruction of woodlands, it did leave a legacy of fine buildings that are seen by most as environmental attributes. The dividing line between what is a negative legacy effect on the environment and what is not is sometimes a fine one to draw and depends on who is being consulted.

Legacy effects occur because of the lack of a full allocation of long-term property rights to resources, which leads to excessive myopia in decision making. The 1987 report of the World Commission on Environment and Development, Our Common Future (the Brundtland Report), emphasizes that sustainable development requires current generations to leave an adequate legacy of resources for future generations. To achieve this goal, individuals have to take responsibility for resources. Without a complete legal definition of who owns these resources, however, it is difficult to ensure that adequate conservation is achieved. If this is not accomplished, then what is known as the “tragedy of the commons” becomes apparent as individuals in each generation excessively exploit resources with no regard to future needs or the implications for future generations.

Dealing with legacy effects poses a variety of public policy challenges. Ideally, property rights should be allocated across generations so that decisions regarding current consumption are made with due cognizance of their implications for future generations. Because the lack of adequate property-rights allocations in the past has burdened current generations with environmental costs, an inevitable degree of remedial action may be justified. In many countries, for example, large sums are being spent on cleaning watercourses where runoff from mining activities prevents plants or fish from living, on removing dams to allow salmon to move upstream, and on reforestation. The general approach to these legacy situations is to apply some form of informal benefit-cost analysis that seeks to weigh the immediate costs of remediation against the social benefits for future generations. In many cases, the financial burden for such measures is spread across communities as the state directly shoulders the burden, but in other cases there may be requirements for particular groups to pay. It may, for example, be necessary for a land developer to clean contaminated soil associated with a previous land use before new construction is allowed. In some cases, this latter approach can actually pass part of the cost back to those who caused the problem; in the land use example, the seller of the contaminated site will get a lower price for it.
The embrace of legacy effects in the public policy process often encounters an informational problem. Technology changes over time, and the long-term environmental implications of any action are difficult to fully assess, particularly when there are major technological or social changes taking place. In general, the world’s current generations are materially better off than previous generations; its members live longer and there is also evidence that in many respects the environment is locally less polluted than it was forty or fifty years ago. Consequently, simply thinking in terms of the costs of future remedial actions to counter ongoing environmental intrusions may produce overestimates. Additionally, there are some current actions now that we do not understand well enough to be able to assess their legacy effects, either negative or positive. The lack of any real indication of the risks involved makes “insurance” policies difficult to formulate in these circumstances, and hence many advocate abstinence from any actions without knowing their full implications.

To combat current environmental effects that we know will be passed on to future generations, a number of micro- and macrostrategies have been adopted. At the micro level, many countries seek to economize on excessive resource depletion by stimulating recycling—for example, by requiring payment of a deposit at the time of purchase of an item, which is refunded when the item is returned for recycling. These initiatives encompass such items as bottles and cans, and even motor vehicles in some Scandinavian countries. There are also various standards that effectively “sunset” any adverse environmental effects—for example, the compulsory use of biodegradable materials for some products, or term limits on fisheries.

Macro legacy effects include global warming and the handling of nuclear products. Both of these are long-term matters affecting generations extending far into the future. They also have international ramifications; the effects represent a legacy with implications for citizens of other countries. Efforts to deal with this type of intergenerational externality have involved the United Nations (e.g., the International Atomic Energy Agency) and a series of global summits (resulting in, for example, the Kyoto Protocol).

**LEGAL SYSTEMS**

A legal system is a mechanism for creating, interpreting, and enforcing laws in a given jurisdiction. The major legal systems in the world include civil law, common law, socialist law, religious law, and customary law. Most nations have incorporated aspects of some or all of these systems, or developed variations on each system, into their own legal system.

**CIVIL LAW**

The civil law system is the predominant legal system in the world. It developed out of Romano-Germanic law—the law of continental Europe—based on a mixture of Roman, Germanic, ecclesiastical, feudal, commercial, and customary law. The beginnings of the civil law tradition can be traced to the Twelve Tables, written in 449 BCE, which laid the foundation for Roman law and would eventually become one of the most advanced systems of law in history.

Following the rise of the nation-state system in Europe, natural or civil codes were established in several countries, including France, Spain, Germany, and several Latin American and East Asian countries. The purpose behind the civil codes was to create a unified system of laws or statutes derived from basic principles and upon which judicial decisions are based. Perhaps the most widely known civil code is the Napoleonic Code established in France in 1804, which is the foundation for the civil law systems of Quebec and Louisiana. The German Civil Code, too, provides the legal foundation for the civil law systems of the former Soviet bloc countries, Japan, South Korea, China, and Taiwan. Most of Latin America also uses the civil law system as a result of the influence of its former colonial masters in Europe.

A distinguishing feature of the civil law system is that it is based on the idea of flexibility and judicial discretion in interpreting the law. Different schools of judicial interpretation exist in most civil law countries, and the law tends to be a product of these competing schools. Judicial disregard of precedent is considered to be a strength of the civil law system because it allows for alternative interpretations of the law that may be more compatible with the facts and circumstances of a particular case. One of the results of this more flexible approach in applying the law is that judicial opinions tend to be more concise, as courts
Legal Systems

discuss only the relevant legislation that applies rather than detailing how a decision was reached. However, the civil law system is still subject to the vagaries and uncertainties of judge-made law where the role of precedent has little influence.

COMMON LAW
Common law systems can be found in many nations that were former colonies or territories of England. The common law originated with the unification of England and the institutional stability provided by William the Conqueror (c. 1027–1087) after 1066. In 1215 King John (1167–1216) elevated the importance of the common law at Runnymede when he signed the Magna Carta. The Magna Carta freed the church, localized the court system, and codified the basic principles of the common law. By the sixteenth century, the common law system had supplanted the civil law system in England, and over time it would become more reliable as a consistent record of case law for judges and lawyers developed.

An important aspect of the common law is the role of precedent or the principle of *stare decisis* (“let that stand which has been stated”). The common law represents the law as expressed by judges in the form of judicial decisions based on precedent rather than statutes. These judicial decisions, if issued by the highest court in a jurisdiction, are binding on all other lower courts within that same jurisdiction. To ensure predictability in the law, high courts are expected not to overturn their own precedents in the absence of strong justification. Though new rules are adopted from time to time and judicial decisions can be overturned, these new rules or decisions also become binding precedents, thus restoring certainty to the law.

In the early twenty-first century, every state in the United States, except Louisiana, utilizes the common law system. Most state statutes provide that the common law, equity, and statutes in effect in England in 1603 be deemed part of the law of the jurisdiction. The common law system also constitutes the basis of the legal systems of Canada (except for Quebec), Australia, Hong Kong, India, Malaysia, New Zealand, and South Africa among other nations. Each of these common law jurisdictions recognizes the importance of the adversarial system and the fundamental principles of law that have been adopted over the centuries by way of custom and precedent.

SOCIALIST LAW
Socialist law is the legal system used in most Communist states. It is based on the civil law system and Marxist-Leninist ideology. During the cold war period, it was incorporated into the legal systems of the Soviet Union and its former satellite states in Central and Eastern Europe. These systems were built on the notion that the state, rather than private individuals, should own most of the property within its jurisdiction.

When the cold war ended and the Soviet Union collapsed in 1989, support for the socialist legal model waned considerably. Some states, such as China, Cuba, Vietnam, and North Korea, continue to practice their own version of socialist law; however, most of these states have modified their legal systems in response to the growing popularity of market-oriented reforms and the inevitable forces of globalization.

RELIGIOUS LAW
Religious law is based on the sacred texts of religious traditions, which advocate norms, principles, or rules as revealed by God that are intended to govern human behavior. Most of the major religions of the world, including Islam, Christianity, and Hinduism, espouse a particular code of ethics or morality that is believed to be required by God and necessary to promote justice within a state. Many nations incorporate religious law into their national legal systems and, in some cases, there is no separation between religion and the state in administering these systems.

Islamic law, or *sharia*, is based on the Qur'an, the primary source of Islamic jurisprudence, and the *sunna*, which purportedly incorporates the practices of the Prophet Muhammad (c. 570–632). Muslims believe that there is no distinction between religious and secular life and, therefore, national laws should reflect Islamic principles. Nations practicing some version of Islamic law in 2007 include Afghanistan, Saudi Arabia, Iran, Iraq, Pakistan, Indonesia, Libya, Morocco, Algeria, Turkey, Egypt, Kuwait, Tunisia, Syria, Sudan, Mauritania, and Lebanon, to name a few.

Canon law is a legal system developed by the Catholic Church and based on the Bible, the foremost source of Christian law. The Code of Canon Law has been compiled, organized, and revised over the centuries to reflect changes in the Catholic Church’s hierarchical, administrative, and judicial practices. Today, the canon law system, which consists of its own courts, judges, lawyers, and legal code of ethics, makes up the legal system of the Vatican in Rome.

Hindu law is a body of rules and principles set forth in the *Manu Smriti* and practiced by the Hindus. It is one of the oldest religious systems in the world and is characterized by beliefs and practices rooted in ancient Vedic culture. Hinduism is the third-largest religion in the world, and its followers are concentrated mainly in India. During the occupation of India by the British, Hindu law was recognized by the British government, but it has been corrupted by the imposition of British common law and secularization.

Other major religious legal systems include the Bahá’í faith (Iran), halacha (Jewish law), Buddhist law (Tibet and Southeast Asia), and Confucian law (China).
CUSTOMARY LAW

Customary law is law developed from the bottom up. It consists of established patterns of behavior that are capable of being observed, and it gives rise to expectations that guide people's actions. An important feature of customary law is that it is not imposed, or handed down, by some coercive institution or individual, but is instead created through mutual recognition and acceptance. Customary law consists of two elements: (1) an observable practice; and (2) a conception that the practice is required by or consistent with a prevailing norm (opinio juris). Customary international law is a type of customary law that refers to the "law of nations" and the rules developed over time as a result of state practice and opinio juris.

LE GUIN, URSULA K.

1929–

Ursula K. Le Guin is a prolific writer of science fiction, children's literature, poetry, and a great many essays and nonfiction works. She was born Ursula Kroeber in Berkeley, California, the daughter of anthropologist Alfred Louis Kroeber (1876–1960), known for his work among Native American tribes, and Theodora Kracaw Kroeber (1897–1979), a psychologist and the author of the best-selling Ishi in Two Worlds: A Biography of the Last Wild Indian in North America (1961). Raised by parents whose professional interests centered on observation and analysis, words, myth, and storytelling, Le Guin developed a fascination with strange worlds and places early on in her life. She submitted her first science fiction piece to Astounding Science Fiction Magazine at age eleven (it was rejected). In 1947 she left California to attend Radcliffe College in Cambridge, Massachusetts, where she received a B.A. in Romance literature in 1951. She continued her education at Columbia University, where she earned an M.A. and a Fulbright Scholarship in 1952. Sailing to France in 1953, she met the historian Charles Le Guin, whom she married in Paris several months later. The couple have lived for more than fifty years in Portland, Oregon, where they raised their three children.

The ostensible uneventfulness of Le Guin's life stands in stark contrast to her extraordinary career and the range and variety of her work. With seventeen novels, eleven children's books, more than a hundred short stories, two collections of essays, five volumes of poetry, and two volumes of translations and screenplays to her name, and having been lavished with numerous literary prizes, including the National Book Award, five Hugos, five Nebulas, the Kafka Prize, and several lifetime achievement awards, she figures as one of the most distinguished writers of her generation. Fighting at the forefront of the civil rights, feminist, and antiwar movements of the 1960s, Le Guin first gained fame with her 1969 novel The Left Hand of Darkness, an exploration of the effects of sexual identity and (non)gender on an androgynous race in an imaginary country set in the distant future. Both here and in her other science fiction works, such as the award-winning The Dispossessed: An Ambiguous Utopia (1974), Worlds of Exile and Illusion (1996), and The Telling (2000), Le Guin puts a strong emphasis on the social sciences, especially on sociology and anthropology, using strange, alien cultures to explore and assess aspects of her own culture.

Praised for her ability to invent credible imaginary worlds populated with highly likeable human and nonhuman characters, Le Guin's work is different from that of other fantasy writers because she is primarily concerned with the human condition. She often uses the alien, nonearthly settings of her stories to present a critical perspective on sociocultural and political issues in our own world, imaginatively exploring new possibilities of living and being in alternative cultures. Politically progressive, witty, and a brilliant stylist, Le Guin has not only gained her reputation as a writer of "speculative fiction": With her nonfiction works, such as Dancing at the Edge of the World: Thoughts on Words, Women, Places (1989) and
Steering the Craft (1998), she has also established her name as an incisive social and cultural critic.

LEISURE
Leisure is not an essential human characteristic or pursuit. Yet it has a history and a variety of cultural manifestations (in language, rituals, and recurring occasions and events) determined by a variety of historical settings. Through its bewildering array of forms, leisure’s only constant is its relation to work. Work and leisure are a mutually defining pair in their origin and through their historical development. Indeed, as work changed, so did leisure.

Originally, and still today among hunters and gatherers, humans had no abstract, general word for subsistence-related activities. The concept of work emerged with humans’ ability to control other humans—primarily with slavery. As humans recognized work as a distinctive cultural reality, so too did they begin to recognize freedom from work and control as leisure.

The combined human concept of work and leisure as “figure and ground” (as a mutually defining, historical pair) is demonstrated by some of the first words for the pair: The Greek word for work (α-σχολία, meaning “not leisure”) was defined by its negative relation to leisure (σχολή), just as the Latin neg-otium (not leisure) was defined in relation to otium (leisure).

In the classical age and the medieval world, leisure was the basis of culture—it represented the privilege of the few founded on the slavery of the many. As Aristotle famously noted, for the rich and powerful, the purpose of work and economic concerns was the freedom to become more fully human by doing those activities that were more complete in themselves, such as the liberal (free) arts, philosophy, politics (including all forms of free civic engagement), contemplation, and celebration. Over the centuries, leisure became so identified with learning and culture that the Greek word for leisure (scholē) developed as the etymological root of words for “school” and “scholarship” in many modern languages.

The positive view of leisure as work’s purpose and fulfillment persisted in the West until the Reformation, when, as a variety of scholars beginning with Max Weber recognized, the cultural valuations of leisure and work became reversed. Weber understood that the modern view of work—summed up as “one does not work to live; one lives to work”—represented an historical revolution (Pieper 1952, p. 40).

After the sixteenth century, what Hannah Arendt called the modern “glorification of work,” and Joseph Pieper described as “the rise of the world of total work” progressively eclipsed leisure as the basis of culture. The spread of capitalism and the marketplace commodified and rationalized leisure as well as work. More and more kinds of previously free activities were drawn into the marketplace, and various products were being produced to be bought and sold.

In the modern age, leisure is no longer widely valued among the newly emerging business classes or their socialist critics as the freedom to realize human potential. Writers such as Thorstein Veblen and Friedrich Engels, defining humanity as “Homo Faber” (man-the-worker/tool maker) insisted that work was the essential human characteristic. Veblen saw leisure as an example of the conspicuous consumption of the rich, a dangerous example for society that tempted its productive members to forget that work was the foundation of human morality and solidarity.

Increasingly, residents of the West have tended to turn from leisure to work as the time to realize their humanity, as the glue that holds humans in society, and as the fundamental moral imperative. However, all have not been true believers in the Protestant work ethic: its later secularized version, the “spirit of capitalism”; or socialist work-utopias. Early in the nineteenth century, as labor was increasingly rationalized and brought into the marketplace, working classes in Europe and America began a struggle for shorter working hours that lasted over a century and cut work time nearly in half.

The primary motive driving this process, one of the longest and most broadly based social movements in the history of the Western world, was workers’ desire to have more leisure to spend with family, friends, and neighbors—and, according to a popular nineteenth-century doggerel, “to do with as we will.” At the beginning of the labor movement in the United States, Philadelphia jour-
neymen carpenters, after striking for a ten-hour work day in 1827, resolved that “all men have a just right, derived from their Creator, to have sufficient time each day for the cultivation of their mind and for self-improvement.” Union leaders regularly repeated these sentiments for over a century, fully expecting that the “progressive shortening of the hours of labor” would eventually elevate leisure to life’s center, reducing “human labor to its lowest terms” (Hunnicutt 1988, p. 322).

Ever since the founding of the United States, myriad believers in progress agreed that industry and the free market must eventually provide all people with enough “necessaries,” as well as the steadily increasing leisure to enjoy them. As early as 1794, the U.S. inventor Samuel Hopkins foresaw a two- or three-hour work day, an expectation repeated regularly until the 1920s and 1930s, when influential scientists and economists such Julian Huxley and John Maynard Keynes confidently predicted, on the basis of a century-long economic trend, that the marketplace would soon provide everyone with all that they might rationally need in exchange for two or three hours of work a day. Before the twentieth century ended, it was believed, leisure would replace the economy as mankind’s primary concern.

Clearly, such predictions were wrong. Instead of the “progressive shortening of the hours of labor,” there has been little or no increase in leisure since the years of the Great Depression. In the early 1990s, the sociologist Juliet Schor presented a persuasive case that leisure had been declining over the previous three decades in the United States. These changes have coincided with the commodification and trivialization of leisure. More importantly, the nineteenth-century and early twentieth-century vision of the expansion of life beyond the pecuniary realm as a logical part of industrial progress has been forgotten.

Instead of following the lead of sociologists, educators, and economists of the early part of the twentieth century, who were trying to prepare the nation for “the worthy use of leisure,” social scientists now assume that leisure is valuable mainly because it contributes to recreational spending, and because it allows people to recuperate for more work and to “adjust” to the pressure of modern life. The millennia-long belief that as humans get enough of the things that money can buy they might then live a fuller and happier life by moving up to freer and better things has been obscured by the modern credo that enough of the things that money can buy they might then live a fuller and happier life by moving up to freer and better things has been obscured by the modern credo that eternal economic growth and perpetual work expansion and job creation are humanities’ summa bona. The concept of “work without end” has replaced the old dream of expanding leisure as humanities’ final challenge.

**LENDER OF LAST RESORT**

All advanced economies have relatively sophisticated banking systems. The commercial banks that make up the system operate on the basis of the *law of large numbers*. They accept deposits in the form of government-issued currency or transfers of cash reserves from other banks. The commercial banks then lend a large fraction of these reserves to businesses and individuals. This means that the claims of depositors against the banks exceed the banks’ holdings in cash reserves by a wide margin. Banks are able to operate in this manner because the law of large numbers is at work. A single bank has a large number of depositors, whose deposit and withdrawal patterns vary widely. On any given day, deposits and withdrawals largely cancel out, permitting banks to meet their necessary net payments with relatively small cash reserves. Banks are able to operate in this manner because depositors are confident that their banks will always honor their requests to transfer funds or make withdrawals.

A system that is based on confidence can collapse if confidence fails. If depositors fear that their bank might be unable to honor all their requests for funds, they may “run on” the bank: The law of large numbers breaks down as depositors attempt to withdraw their funds from the bank. Since most of the bank’s assets are tied up in loans
that cannot be sold quickly to other financial institutions, the bank may have to stop payment.

In general, bank runs stem from one of two sources. Runs on individual banks may occur when depositors suspect that a bank is insolvent, that is, its net worth is negative. If the bank is in fact solvent (it has positive net worth), it should be able to borrow cash from other banks, enabling it to weather the run. General bank runs, affecting all banks in an area or throughout the economy, occur when depositors fear that the failure of other banks will trigger the failure of their own banks. Thus, depositors have the incentive to run on solvent banks. Because the bank run is general, individual banks cannot borrow from other banks, which are also under pressure. In the absence of a bank able to inject large quantities of legal currency into the banking system, the entire system is liable to collapse. A bank able to provide currency to the banking system in such situations is called a lender of last resort.

The importance of a lender of last resort to the banking system was recognized in 1797 by Sir Francis Baring (1740–1810), a London financier, and Henry Thornton (1760–1815), a London banker. Both argued that the Bank of England should respond to a large increase in the demand for currency by the English public by increasing the amount of currency issued by the bank. Failure to meet the increased demand for currency would drain liquidity from the financial system, causing many solvent financial firms to fail. Widespread financial failure would be followed by an economic downturn.

Although the Bank of England did, on occasion, play the role of a lender of last resort (O’Brien 2003), the bank’s directors rejected calls to formally accept the role of lender of last resort, even after Walter Bagehot (1826–1877) made the classic case for it in 1873 (Bagehot [1873] 1999), further developing Thornton’s ([1802] 1939) analysis. The bank’s directors argued that promising to act as the lender of last resort would prompt banks to take on more risk, a behavior known as moral hazard. The result would be perverse: a lender of last resort might lead to more bank failures. In subsequent decades, the Bank of England held no larger gold reserves than it had before, refusing to commit to serve as Great Britain’s lender of last resort.

One of the purposes in establishing the Federal Reserve System in the United States was to improve the ability of the U.S. monetary system to meet increases in the demand for currency. Before 1914, the United States did not have a central bank, and increased demand for currency by rural banks during the harvest season resulted in several banking crises. The creation of the Federal Reserve System made it possible for commercial banks to obtain reserves by using short-term commercial loans as collateral for loans from the Federal Reserve banks. The United States experienced no liquidity crises from 1914, when the Federal Reserve System began operations, until the early 1930s, when the Federal Reserve’s failure to respond to large increases in the demand for currency contributed to the failure of more than ten thousand banks and to the severity of the Great Depression. Following the lead of Irving Fisher (1867–1947) and Henry C. Simons (1899–1946), Hyman Minsky (1919–1996) developed an argument in favor of a lender of last resort based on a financial fragility hypothesis. Minsky argued that overextension of credit by the banking system could lead to a general collapse of credit in the absence of a lender of last resort. In the post–World War II period, the Federal Reserve has acted on several occasions to prevent liquidity crises from developing.

LENIN, VLADIMIR ILITCH
1870–1924

Vladimir Ulianov was born in 1870, and in the 1890s he chose Lenin as his revolutionary pseudonym. Lenin formed the Bolshevik Party in 1903 and used it to conduct a Communist revolution in November 1917. As the first leader of the Soviet Union, he consolidated power and introduced a socialist system.

At a time when Western Marxists rapidly were deciding that socialist goals could be achieved through parliamentary action, Lenin firmly rejected Western democracy as a way of improving the lot of the workers. Conceding that workers were attracted to short-term economic gains, Lenin insisted in What Is to Be Done? (1901–1902) that a
Leninism

The term Leninism refers to the political and economic ideas associated with Vladimir Ilyich Lenin (1870–1924), leader of the Russian Bolshevik Party and of the Soviet Union following the revolution of October 1917. Lenin saw himself as a follower of Karl Marx (1818–1883) and sought to give Marx’s ideas practical expression.

In What Is to Be Done? (1902), Lenin advocated the formation of a disciplined and centralized organization of professional revolutionaries in Russia to agitate for socialism, rather than the looser grouping favored by other Russian Marxists. Initially, he viewed this as necessary only because of the need to organize clandestinely in czarist Russia, where revolutionary groups were illegal, but later he generalized this model. Lenin argued that it was necessary in all advanced countries to build parties consisting of the most militant and class-conscious members of the working class in order to combat ruling-class ideology and overcome divisions between workers. This revolutionary vanguard would have the clarity of purpose and independence of action necessary to win a majority to its program during a period of major political and economic crisis, and to lead a successful socialist revolution.

Lenin’s Bolsheviks put his theory into practice in Russia during the course of 1917, but within a few years the government.
revolution that they led had degenerated into a one-party regime that bore little resemblance to the ideal of workers’ democracy defended in his State and Revolution (1918). Lenin’s critics see this as proof of an undemocratic impulse in his basic outlook, while his defenders argue that the revolution’s degeneration was a consequence of adverse circumstances, including a brutal civil war, economic collapse, external threats, and the failure of revolution to spread successfully to more economically advanced countries, such as Germany. Certainly before the early 1920s there was always much disagreement, discussion, and debate in Lenin’s party, in sharp contrast to the monolithic dictatorship that developed under his successor, Joseph Stalin (1878–1953), and to the practice of most Communist parties around the world that claimed, following Stalin, to be committed to the tenets of Marxism-Leninism.

Among Lenin’s most influential theoretical contributions is his analysis of imperialism and war. Drawing on the work of the British economist J. A. Hobson (1858–1940), Lenin argued in Imperialism: The Latest Stage of Capitalism (1917) that the imperialist expansion by the world’s major powers in the late nineteenth century was an outgrowth of the development of monopoly capitalism, in which economic power in the advanced countries is increasingly concentrated in a relatively small number of large firms, industrial capital merges with big banks, and there is growing integration of private companies and the state. Competition between capitals for markets thus gives rise, on Lenin’s account, to military and territorial competition between nation states, which he viewed as the underlying explanation of the world war that broke out in 1914. On this analysis, rivalries and wars between major powers are rooted in the dynamic of capitalist development itself, and can only be eliminated by radically restructuring the economic system and replacing capitalism with socialism.

LEONTIEF, WASSILY
1905–1999

Wassily Leontief was born into an academic family on August 5, 1905, in Saint Petersburg, Russia. He earned his undergraduate degree from the University of Saint Petersburg. Upon completing his doctoral dissertation at the University of Berlin in 1928, Leontief started his professional life at the Institute of World Economics at the University of Kiel. He moved to the United States to work for the National Bureau of Economic Research in 1931 and then Harvard University in 1932. He served as the director of the Harvard University Research Project until 1973. Leontief left Harvard for New York University in 1975 to found the Institute for Economic Analysis. He was awarded the Nobel Prize in economic sciences in 1973.

Leontief’s greatest achievement was the creation of a new area of economics, namely input-output analysis. In 1941 he published the classic Structure of American Economy, which laid the foundation for what is now known as a social accounting matrix. Such a matrix gives a snapshot of all transactions in an economy between and within producing sectors, households, factors of production, institutions, and consumers at a level of disaggregation permissible by the availability of data.

Leontief was one of the first to discuss the issue of simultaneous estimation of demand and supply curves and the problems of identification. His work on aggregation and index numbers (1936) has also had a lasting impact. Leontief was one of the early contributors to the theory of aggregation in production relations (1947). He derived conditions under which one can identify structural mathematical relationships from reduced-form equations. His empirical research on the pattern of trade in the United States (1953) led to the well-known Leontief paradox. Later in life, he wrote on a number of diverse subjects, including the environment, population growth, automation, and defense.

The common thread in all his works was his love of general equilibrium analysis and his attempt to provide an empirical foundation to the theoretical work of the French economist Léon Walras (1834–1910). Leontief went well beyond that and brought the role of intermediate inputs to the forefront.

Input-output analysis was developed on the premise that different sectors of production in an economy are interconnected via production relations. One of the fundamental concepts in input-output analysis is the distinction between direct and indirect input requirements. This distinction led to the Leontief multiplier, which gives the total inputs required to produce a given level of final use as the sum of direct requirements and an infinite series...
(first round, second round, etc.) of indirect requirements. A sector can be more labor intensive (or, more polluting) than another in terms of the direct coefficient, but less so in terms of the total coefficient.

The Heckscher-Ohlin theorem on international trade suggests that a country should export goods that use more intensely the factor of production in which the country is relatively abundant; a country should import goods that use more intensely the factor of production in which the country is relatively less abundant. For example, China, which is relatively more abundant in labor, should export labor-intensive goods, whereas the United States, which has relatively more capital, should export capital-intensive goods. Using a 1947 input-output table for the United States, Leontief (1953) found an apparent contradiction between reality and the predictions of the Heckscher-Ohlin theorem. Leontief showed that the United States was apparently exporting labor-intensive goods. The Leontief paradox arises if one uses total coefficients (rather than the direct coefficients) in deriving labor and capital requirements. Direct coefficients are defined per unit of output, but the total coefficients are defined per unit of final use. Leontief made this distinction very clear. He lists the two as “requirements per million dollars of output” and “requirements per million dollars of final output.” He defined capital and labor requirements for competitive imports as those that would be required if the imports were replaced by domestic production. Leontief found that capital and labor (“man” years) per million dollars of U.S. exports in 1947 were 2,550,780 and 182,313 respectively (in U.S. dollars and 1947 prices). The corresponding figures for competitive imports were 3,091,339 and 170,004 respectively. Thus the capital-labor ratio for a million dollars worth of exports is smaller than the capital-labor ratio for a million dollars worth of competitive imports.

The similarity between the Marxian labor theory of value and input-output analysis has led some to speculate that Leontief was influenced by Karl Marx (Bailey 1994). Perhaps Leontief was influenced indirectly by Marx, but it is more likely that both Marx and Leontief had a common source of inspiration in the French physiocrat François Quesnay (1694–1774), who considered a three-way classification of the French economy—farmers, manufacturers, and landowners.

within and outside of the New Model Army (NMA), which had been formed in 1645 by Parliament in the course of the Civil War/Revolution against Charles I. Yet the Levellers are notoriously difficult to pin down, due in part to the heterogeneity of their composition, the shifting nature of their demands, and the fact that the group of radicals the term is understood to designate rejected the appellation.

The Levellers arose out of agitation for the release of John Lilburne (1615–1657). Lilburne had been a radical cause célebre under King Charles I (r. 1620–1649), who had him publicly whipped, pilloried, and imprisoned in 1638 for publishing Puritan tracts. Lilburne was released from prison in 1641 and became a soldier in the Parliamentary army. He was imprisoned again in 1644 for advocating liberty of conscience and the interests of common soldiers, both of which would be successful planks in later Leveller agitation.

In what is generally understood to be the founding document of the Leveller movement, Richard Overton and William Walwyn published *A Remonstrance of Many Thousand Citizens* in 1646. They demanded the release of Lilburne and listed a number of political and social demands that would become the backbone of Leveller ideology. Most significantly, the *Remonstrance* demanded annual parliaments, an expansion of the voting franchise, a form of progressive taxation, the abolition of the House of Lords, liberty of religious conscience, and a written constitution.

Though the Levellers propagated with success among civilians, their greatest inroads were made in the New Model Army, which at this time had become the de facto government of England. They combined the political concerns of the *Remonstrance* with the concerns of the army, including inaction on back pay and the failure of Parliament to produce amnesty for acts committed during the Civil War. Plans to disband the NMA and raise a new army for the invasion of Ireland made these concerns more acute, as they threatened to eliminate the political clout of the army.

The NMA Levellers elected Agitators, or New Agents, from each regiment to press these concerns, and with Overton, Lilburne, and Walwyn they produced *The Case of the Armie Truly Stated* and the *Agreement of the People* (1647), vowing that the army would not disband or be deployed until their demands were met.

The tracts were debated at Putney in October and November of 1647, with much of the debates centered around the franchise. Oliver Cromwell, Henry Ireton, and a handful of officers represented the Grandees (the officers of the NMA) against the Agitators, with Ireton taking the lead. Ireton began the attack by cynically arguing that the Agitators had presented a “levelling” scheme (hence the term) that would result in “communism” and ultimately “anarchy.” He claimed that the *Agreement*, if adopted, would extend the franchise to persons (including “foreigners”) “with no interest” (as manifested in land) in England, and that it would therefore threaten the country’s stability. The Agitators responded that they had risked their lives in war, and thus had more “interest” in England than those who had merely risked land. Though arguments for universal manhood suffrage were made, this does not seem to have been the general aim of the Agitators, and such arguments appear for the most part specifically related to suffrage among soldiers.

The general mood of the Agitators tended toward suffrage of persons considered “independent” (i.e., holders of small property) and did not include such persons as “servants and beggars.” This position met with surprising success among NMA officers, including Colonel Thomas Rainborough, who became an eloquent spokesman for their cause. On the whole, the Agitators’ aims may be summed up in their oft-repeated self-designation—they were for “liberty and propriety,” as opposed to “community and levelling.”

Though the *Agreement* enjoyed the support of a wide swath of officers and rank-and-file soldiers, it was scuttled by a familiar Cromwellian combination of force, fraud, and circumstance. The Levellers ceased to be a political force after 1648. The terms *leveller* and *levelling*, however, almost immediately entered the political lexicon, mostly on Ireton’s terms. As early as 1649, the term *leveller* was in use by Gerrard Winstanley and William Everard, the founders of the Digger colony at St. George’s Hill in Surrey, which sought to lay the foundations of a communist society. The group alternately referred to themselves as “True Levellers.” A popular Ranter named Abiezzer Coppe decried the murder of the “Levellers (so called)” and (in a typically apocalyptic flourish) promised that, as a result, the risen Lord was now going to “levell … in good earnest.”

Though Leveller arguments could, in part, be seen at the root of John Locke’s *Two Treatises* and other Whig thinking, the terms *leveller* and *levelling* came to represent a sort of radical redistribution of political and economic power, usually synonymous with anarchy. As such it was something of a “hot potato” for those so accused, with the notable exception of the eighteenth-century revolutionary Irish underground organization called the White Boys, who also referred to themselves as Levellers.

The term enjoyed a renaissance of sorts in England around the time of the French Revolution. Elites bankrolled societies for “the Preservation of Liberty and Property against Republicans and Levellers,” with “republican” replacing “community.” Edmund Burke categorized republican agitation as “mad” levelling schemes that
sought to “pervert the natural [i.e., hierarchical, hereditary] order.” Levelling thus retained a strong association with “anarchy,” “chaos,” and rule by the “rabble.” The radical pamphleteer Thomas Paine, whose writings owe a deep (if unwritten) debt to the seventeenth-century Levellers, sought to distance himself from such accusations and turn them on his critics, arguing that a hereditary aristocracy was itself a levelling scheme that ignored merit and elevated the bad, corrupt, and incompetent to positions of power by virtue of birth.

If Paine sought to distance democratic reform from accusations of levelling, plebeian revolutionaries who followed in his wake were less skittish regarding the term, which was used interchangeably in such circles with radical reformer. The radical writer Thomas Spence (1750–1814) derived some of his ideas regarding land redistribution from the Diggers, or True Levellers, and he was publishing excerpts from seventeenth-century Leveller writings in his Pig’s Meat, or Lessons for the Swinish Multitude in the late eighteenth century. In Spence’s example, British ultra-radicals reveled in accusations of levelling (and in being part of the “swinish multitude”). The publisher Samuel Waddington’s Medusa, an ultra-radical publication, spoke approvingly of “levelling,” as did the poet Richard “Citizen” Lee, who, perhaps confirming reactionary fears, combined the term with an affection for the guillotine. The wildly popular ultra-radical preacher (and son of a slave) Robert Wedderburn was enormously fond of metaphors of levelling, and he was tried for seditious blasphemy in 1819 partly for linking Jesus Christ with such concerns.

Levelling tended to fall from use in the nineteenth century, when it was replaced by radical, socialist, communist, and other terms that reflected the political landscape of the time. The seventeenth-century Levellers became a subject of great interest both for socialist and Whig historians in the early twentieth century after the discovery of Clarke’s minutes of the Putney Debates. These permitted a serious appraisal of just what the Levellers had stood for, and the term has lost its pejorative sense as many of their demands have been achieved and even superseded.

LEVERAGE

Leverage is the indebtedness of a company, or the process of increasing the indebtedness of a company (as in the phrases “highly leveraged company” or “acquiring leverage”). It is usually measured by one of two gearing ratios. Capital or financial gearing is the amount of debt that a company has relative to its total capital. Alternatively, income gearing is the ratio of a company’s debt to its total income.

Until the twentieth century, income gearing was the common measure of leverage. This reflected a corporate practice in which the only possible gainful use of debt—that is, aside from its traditional unproductive use in financing consumption or government—was to finance commerce or industry. It followed that the key indicator in determining the amount of borrowing was the possible income that it might generate in trade or production.

With the emergence of active markets in corporate finance toward the end of the nineteenth century in Britain and the United States, the scope for the gainful employment of leverage extended beyond commerce and industry, and into the capital market itself. Once that market became sufficiently large, the return from profitable trade in it was determined by the total amount of capital that could be turned over in that market. In these circumstances, the major consideration was no longer possible future income in trade or production, because these are irrelevant in determining income from arbitraging in the capital market, but the amount of capital that could be applied to a profitable arbitrage. That amount of capital, and hence the income from it, was maximized by adding borrowing to equity. From this emerged the measure of leverage common today, namely the ratio of debt to total capital.

The roots of this change in definition, in the changing business of finance, was obscured in the 1950s by the
famous Modigliani–Miller theorem, which claimed to prove that the value of a corporation is not affected by the division of its capital into equity and debt. But this is under the assumption of a perfect capital market, with no arbitrage possibilities, so that the return on debt was ultimately provided by income from commerce or industry, rather than further financial transactions. The “theorem” set off a number of hares in the academic finance literature to determine whether variations in leverage were caused by capital market imperfections or differences in the tax treatment of interest on debt, as opposed to the tax liability on the return to equity.

By the mid-2000s it was increasingly recognized that the business opportunities available to a company and its liquidity are clearly affected by its leverage. A company with $1 million of equity, tied up in productive equipment and work in progress, is a relatively illiquid company that may experience financial difficulties if a larger than expected bill needs to be paid. That same company with an additional $10 million of debt invested in the money market is a highly liquid company that can cope with larger-than-expected payments. Such a company can undertake new projects without having to waste management time in finding financial backers. Most importantly, it can itself engage in speculative buying and selling of companies in the capital market without reducing its liquidity, as long as that market stays liquid. With the expansion of capital market financing beyond the United States and United Kingdom into Europe and emerging markets elsewhere, leverage is becoming an increasingly widely used way of making medium-sized businesses into large corporations without the tedium of expanding productive or commercial capacity.

LÉVI-STRAUSS, CLAUDE

1908–

Anthropologist and philosopher Claude Lévi-Strauss, one of the leading figures in structuralism, was born in France in 1908. He studied philosophy in Paris and taught sociology at the University of São Paolo, Brazil, from 1934 to 1938. During these years, Lévi-Strauss traveled in Brazil and lived intermittently with the Amazonian tribes, especially the Nambikwara. The result of this early contact of Lévi-Strauss with pre-capitalist societies formed the basis of his first book, The Elementary Structures of Kinship (1949). He returned to Paris in 1939 to fulfill his military service requirement but had to flee France and the advancing Nazi threat, a flight that brought him to New York. In New York, he lectured at the New School for Social Research and came into contact with the linguist Roman Jakobson (1896–1982), with the Department of Anthropology at Columbia University and the anthropologist Franz Boas (1858–1942), and with the fieldwork- and practice-oriented American anthropology.

The encounter with Jakobson proved decisive for the development of Lévi-Strauss’s structuralism. Taking from Émile Durkheim (1858–1917) the notion that religion is part of a symbolic system of human understanding of humanity, Lévi-Strauss developed the theory of human culture as a logical, coherent, but unconscious system of interlocking symbolic subsystems (such as religion, kinship, mythology, and economics). Elaborating further on Marcel Mauss’s (1872–1950) theory of gift exchange as a local theory of reciprocity, Lévi-Strauss was able to expand his analysis of symbolic exchange to include marriage and kinship patterns. Jakobson’s theory of structural linguistics brought all these theorizations of Lévi-Strauss into a neat package that claims to explain human behavior and culture as an intricate system of analogies between the tactile and the symbolic universe of humanity. His whole scheme of explanation rests on the fundamental notion of Jean-Jacques Rousseau (1712–1778) of savage nobility, where the true nature of the human is only to be found in the state of nature, prior to the corruption of the human by civilization and the development of private property. Lévi-Strauss’s indebtedness to Rousseau is evident both in his autobiographical work Tristes tropiques (1955), one of the most eloquent and beautifully written books in anthropology, and in The Savage Mind (1962), the English title an inadequate translation of the original French La Pensée sauvage, with its double meaning of “thinking savage” or “wild pansy”).
Lévi-Strauss's structuralism owes its foundational premise to Jakobson and Russian linguist Nikolai Trubetzkoy’s (1890–1938) elaboration on the significance of phonemes for linguistic structure. Jakobson and Trubetzkoy had shown that phonemes provided linguistic structures with a specific economy of terms of meaning, and that the relationship between those terms is more significant than the terms themselves. Therefore the relationship between the terms that signify death, for instance, is a universal constant, despite the fact that the specific terms are universally different. One way of detecting the significance of the relationship of terms, Lévi-Strauss claims, originally in his three-volume Mythologiques (1964–1968) and later in The View from Afar (1983), is by looking at myths that are universally constituted by mythemes (analogous to the linguistic phonemes). These mythemes, despite the fact that they appear in different terms in the myths encountered throughout the world, underline the fact that all societies have engaged in the deciphering of the foundational question, which for Lévi-Strauss is always the same, namely, the riddle of the transition from nature to culture, from animality to humanity. Thus myths are the results of unconscious explanations about the origins of humans. The insularity of structuralism as a theory of explanation prompted anthropologist Clifford Geertz in his The Interpretation of Cultures to proclaim that Lévi-Strauss has “made for himself an infernal culture machine” (1973, p. 355).

Lévi-Strauss lives in Paris. He has taught for many years at the Collège de France and in 1973 was elected to the Académie française.

complex changes in the social and physical environment. Theories focusing on complex intrapsychic processes and equally complex experimental manipulations were Lewin's unique contributions to the psychology of his time, as well as his legacy in the psychology that would develop after his death. Two books, *A Dynamic Theory of Personality* (1935) and *Principles of Topological Psychology* (1936), provide systematic treatments of his approach. His many experimental reports display his innovations in research methods. Early criticisms of Lewin's work focused on the difficulty and unfamiliarity of the concepts he employed, as well as the complexity of the experimental protocols he used. Over time, these criticisms faded as the psychological issues he explored became important research topics, while the details of his theoretical work received less and less attention. His style of experimentation was adopted by his students and colleagues, notably Leon Festinger (1919–1989), and became a robust tradition in social psychology.

Lewin had a lifelong dream of establishing a research institute that would conduct applied research focused on social issues such as prejudice, intergroup conflict, and social change. He succeeded in establishing the Research Center for Group Dynamics at MIT in 1944, and the Commission on Community Interrelations for the American Jewish Congress in 1945 in New York. An outgrowth of this work was the development of the National Training Laboratories, within which the T-group, or sensitivity training, was created.

Lewin is regarded by many social psychologists as the father of their discipline. He is certainly one of the field's towering ancestral figures, for two reasons. His unique combination of theory with bold experimentation provided the conceptual and methodological tools to study complex human social interaction. And, from his days in Berlin until his death in Massachusetts, he attracted and inspired dozens of students who used those tools to develop many of the central theories and findings in social psychology, including group dynamics, level of aspiration, social comparison processes, and action research.

**LEWIS, OSCAR**

**1914–1970**

The anthropologist Oscar Lewis is best known for devising the “culture of poverty” theory and applying the life history and family studies approach to studies of urban poverty. The concept of the culture of poverty is cited often, especially in the popular press, and at times it is misapplied as an argument that supports the idea of “blaming the victim.” Not surprisingly, given the continuing salience of debates about the causes of poverty, Oscar Lewis’s legacy within anthropology and the social sciences is still very much debated. Indeed, the notion of a “culture of poverty” has since reemerged in discussions of the “urban underclass.” While most researchers view the causes of poverty in terms of economic and political factors, there is still a strain of thinking that blames poverty on the behavior of the poor.

Oscar Lewis was born on December 25, 1914, in New York City, and he was raised in upstate New York. He received a BA in history from the City College of New York. While in college he met his future wife, the former Ruth Maslow, who would also become his co-collaborator in many of his research projects. He enrolled in graduate school in history at Columbia University, but under Ruth Benedict’s guidance he switched to anthropology. Partially due to a lack of funding, his PhD dissertation on the impact of white contact on Blackfoot culture was library based. After graduating he took on several jobs, including United States representative to the Inter-American Indian Institute in Mexico, which led him to begin conducting research on the peasant community of Tepoztlán. Lewis’s critique of Robert Redfield’s 1930 study of the same village is considered a classic in Mexican anthropology. Lewis’s research shows, in contrast to Redfield’s, that peasant culture in Tepoztlán is not based on “folk” solidarity but is rather highly conflictual, driven by struggles over land and power. In 1948 Lewis joined the faculty at the University of Illinois at Urbana-Champaign, where he was one of the founders of the anthropology department.

During his tenure at Illinois, Lewis produced his best-known works including *Five Families* (1959), *The Children of Sánchez* (1961), and *Anthropological Essays* (1970). In both *Five Families* and *The Children of Sánchez*, Lewis describes the culture of poverty theory and provides rich insights on urban poverty in Mexico through the narratives of his informants. In *Anthropological Essays*, Lewis reiterates the culture of poverty theory, which at its most basic level is an adaptation to economic circumstances: “The culture of poverty is … a reaction of the poor to their marginal position in a class-stratified, highly individuated, capitalistic society” (Lewis 1970, p. 69). Included in Lewis’s trait list of the culture of poverty are feelings of inferiority and aggressiveness, fatalism, sexism, and a low
level of aspiration. Lewis saw the culture of poverty as resulting from class divisions, and therefore present not only in Mexico but throughout the world.

Because Lewis’s description of the poor went against the clean-cut image presented by the Mexican media, there was, within Mexico, harsh criticism of the notion of a culture of poverty. This response, as Miguel Díaz-Barriga (1997) points out, obfuscates the overlap between Lewis’s representations of the urban poor and Mexican social thinkers such as Samuel Ramos and Octavio Paz. Díaz-Barriga shows that in their interviews, many of Lewis’s informants ironically played off of well-known stereotypes of the urban poor, and that Lewis took their statements literally.

In the United States, the culture of poverty theory became well known through its application in Daniel Moynihan’s 1965 report for the Department of Labor, The Negro Family: The Case for National Action, which informed national policymaking, including Lyndon B. Johnson’s War on Poverty. By focusing on the “pathologies” that emerged from slavery, discrimination, and the breakdown of the nuclear family, Moynihan saw the emergence of a culture of poverty among the African American poor. This emphasis on the pathologies of poverty has since been reframed in terms of theories of the urban underclass that seek to understand the urban poor as being both economically and culturally isolated from the middle-class. While sociologists such as William Julius Wilson (1980) have devised sophisticated understandings of the urban underclass, this concept, especially in the popular press, has become a stand-in for arguments that see the causes of poverty in terms of cultural pathologies.

In their well-known 1973 refutation of the application of the culture of poverty theory, Edwin Eames and Judith Goode argued that many of the characteristics associated with poverty, including matrifocal families and mutual aid, are rational adaptations. The continuing prevalence of poverty, they stated, must be understood in terms of restricted access to and attainment of job skills. Studies that pathologize the poor have received justified criticism for privileging middle-class values, being vague about the overall characteristics of poverty and their inter-relations, and viewing matrifocal households as being a cause rather than a result of poverty. The historian Michael Katz argues that, when given educational and employment opportunities (instead of dead-end service sector jobs), the urban poor aspire to succeed as much as their middle-class counterparts. Katz convincingly calls for a historical understanding of the educational, housing, and economic policies that have generated urban poverty.

As evidenced by essays marking the fortieth anniversary of the Moynihan Report in the popular press, many continue to believe that the culture of the poor must be understood as a cycle of broken households and disruptive behavior. This renewed cycle of applying the culture of poverty theory represents the pathological ways that American society has sought to overcome class-based and racial inequalities. Indeed, it is easier to blame the poor for their poverty than to do the hard work of understanding the historical and economic factors that have generated poverty and the policy options that can transform cities.

When Oscar Lewis died, on December 16, 1970, social scientists were beginning to forcefully criticize his work for blaming the victim. Lewis’s death at fifty-five years old was particularly untimely because he was not able to respond to these critiques. Indeed, the social sciences lost an opportunity to engage Lewis’s responses and, perhaps, reach agreement on more fruitful ways to explore urban poverty.

LEWIS, W. ARTHUR
1915–1991

William Arthur Lewis was quintessentially Caribbean. Born on January 23, 1915, in colonial St. Lucia of immigrant Antiguan parents who were both schoolteachers, he spent much of his life living in Britain or the United States but working on the problems of the Caribbean, Africa, Latin America, and Asia. In 1933, on a government scholarship, Lewis went to the London School of Economics (LSE) to do the Bachelor of Commerce degree. He graduated with first-class honors in 1937 and received a scholarship to do the PhD in economics, which he completed in 1940. In 1979, Lewis shared the Nobel Prize in economics with Theodore Schultz for pioneering research into economic development, in particular the problems of developing countries.

Lewis’s great achievements were in economics, but he also had a distinguished career as an administrator. He was UN Economic Adviser to Kwame Nkrumah, the prime minister of Ghana, deputy managing director of the UN Special Fund, vice-chancellor of the University of the West Indies (1960–1963), and founder of the Caribbean Development Bank (1970–1974). By his account, this experience taught him more about policy than economics and motivated his publications on development planning. Scholarly enrichment came from his travels (Lewis 1994, p. xlviii).

Lewis published extensively on industrial economics after 1937, then published Overhead Costs in 1948 and dropped the subject. In 1948, at age thirty-three, Lewis became a full professor at the University of Manchester. There, he tackled development economics, addressing: (1) the fundamental forces determining the rates of growth of agricultural and industrial countries or sectors; (2) the relative price of agricultural and industrial products; and (3) distribution—the adjustment of the real wage rate and wage share of output as capital accumulates. As Lewis tells it, one day in August 1952, on the road in Bangkok, he saw the common solution to these problems: Use the classical assumption of “an unlimited supply of labor” available to a capitalist sector from an indigenous noncapitalist sector “at subsistence wages” (Lewis 1992). Unlimited supplies keep the wage low and fairly constant and generate a high rate of profit and a low relative price of agricul-
tural output. They also allow creation of new capital with technological progress, a rising rate of profit and savings, and expanded employment and output in the capitalist sector without raising consumption per worker. This initially causes faster growth in industrial countries because they reap all the benefits of technological progress. However, as industrial countries face rising wages, they export capital and encourage immigration, thereby allowing the growth rate of surplus labor countries to catch up. How much growth these capital exports generate for surplus labor countries depends partly on their natural resources, capital stock, demand in industrial countries, and the terms of trade. Lewis published this solution in his classic 1954 article, “Economic Development with Unlimited Supplies of Labour.”

In 1963, Lewis took up a new professorship of political economy at Princeton University, a position he held until his death on June 15, 1991. At Princeton, Lewis used the growth channel of his “unlimited supplies” model to clarify the evolution of the international economic order since 1870. Trade is the principal link through which growth of industrial countries causes growth of the labor-surplus countries. Moderated growth in industrial countries causes slower growth of surplus-labor countries, unless an alternative growth engine is found. One option is a greater share of the markets of industrial countries, but this is unreliable. Preferable is growing trade among surplus-labor countries. This alternative trade engine could arise if a sufficient number of the large surplus-labor countries, such as India and Brazil, can end trade dependence on industrial countries, achieve self-sustaining growth, and provide alternative markets to the others. Lewis published these findings in his book The Evolution of the International Economic Order (1978) and his 1980 Nobel Lecture, “The Slowing Down of the Engine of Growth.” By his logic, the current explosion of growth in excess of 7 percent per annum in Brazil, China, and India should provide much stimulus for the development of other surplus labor economies.

Lewis’s Bangkok inspiration was rooted more firmly in influences of economic historians of the British nonrevolutionary socialist Fabian Society. Leading earlier members Barbara and J. L. Hammond (1917) had argued that the English industrial revolution was possible mainly because the emerging bourgeoisie could attract a large redundant rural labor force into urban industrial activity at low and constant wage rates. Lewis’s firsthand knowledge of the Caribbean and observations of Egypt and Asia convinced him that a similar exodus could also underwrite an industrial revolution in those and similar countries where many nonindustrial subsistence workers contribute a zero or negative marginal product. However, an attendant condition was active trade unions and an emerging class of entrepreneurs or an active government operating...
democratically and dedicated to making and accumulating capital. Lewis (1949) summarized the main arguments in a Fabian pamphlet, foreshadowing the arguments of the 1954 paper.

From the start, economists questioned the updated classical assumption, the assumption that surplus labor only creates new capacity within the capitalist sector, along with Lewis's pessimism about the ability of surplus-labor countries to win a greater share of developed-country markets. Schultz (1964) used neoclassical data, competitive conditions, the assumption of rationality, and evidence from Egypt and Asia to argue that the marginal product of labor is neither zero nor negative. With transformation of traditional agriculture, rural wages could fall low enough relative to the marginal product in agriculture to enable full employment. Lewis's views amounted to assuming either an uncompetitive market or a distorted preference for leisure among agricultural workers.

Lewis himself viewed peasants as hardworking and thrifty and held that the main problem was a capitalist sector that is too small or disinclined to transform agriculture by accumulating capital (Lewis 1936, 1949, 1954, 1955, 1968, 1979). Amartya K. Sen (1966) also objected to Schultz, citing contrary evidence for India and observing that Lewis's assumption really means that the marginal product in the capitalist sector is greater than the average product of the subsistence sector. Nevertheless, Lewis's essential difference with Schultz on the capitalist wage is that its floor is set by the average productivity of the self-employed. As William Darity (1984) observed, Lewis employed an economic anthropology of traditional agricultural systems. Subsistence workers were household and community members who could not be easily dismissed without damaging established family and social norms. They could opt for the average benefits of the family operation rather than a lower capitalist real wage and thereby cause a breakdown of Adam Smith's law of demand.

Perceptive critiques of Lewis also came from the Caribbean. In three major proposals on Caribbean industrialization, Lewis proposed attracting multinational corporations to lead the process (Lewis 1950, 1951; UN 1951). Lloyd Best lampooned the strategy, naming it "industrialisation by invitation" and calling Lewis an "Afro-Saxon" (Best 1999). Multinational corporations would continue to import labor-displacing capital, re-create surplus labor, repatriate high rents, avoid the push for good governance, and promote repression of radical labor and neglect of the peasantry, as Lewis himself had complained (Lewis 1936). More important, the subsistence sector included viable entrepreneurs and collaborators producing and accumulating capacity and trading with the capitalist sector, not as pain and trouble but for the pleasure of building an alternative to the legacies of slavery and strict indenture. The market for labor was tighter than Lewis implied and rising real wages were inevitable (Best 1975). Once import substitution started in the Caribbean, this became evident, but Lewis found it perplexing (Lewis 1958, 1968).

Yet Lewis's formulations can accommodate the Caribbean critique. His geometry of the marginal product of labor features diminishing returns to capital scarcity and an implicit production function that may not be algebraic and is dynamic, taking into account net capital accumulation, technical progress, increasing returns, and an underlying multiplier linked to the capitalist employment rate and the ratio of the marginal product of labor to its maximum. It allows residual profit at a rate different from the marginal product of capital and an independent distribution identity, and can be updated to account for rents on imported capital and production and accumulation of domestic capacity. With deliberate domestic capacity creation and supporting policy for their indigenous sectors, abundant externalities and stabilized rentals on imported capacity can replace Lewis's cheap constant wage as the driver of the savings mechanism, and surplus-labor countries need not be pessimistic about winning higher market share in industrial countries over time in the context of rising real wages. These adjustments would still be consistent with Lewis's view of how to achieve balanced growth, clarified in his 1949 note on "Colonial Development" in United Nations (1951) and in Lewis (1954, 1964). So, Lewis's independent marginal product function and his associated price, distribution, and growth theories represented major steps in clarifying how surplus-labor countries grow and the wider world economy evolves. They hold as limiting cases, providing an updated classical alternative to the increasingly dominant neoclassical theory of growth and trade, and they still apply to many countries of the world today. Viewed in this light and his time, Arthur Lewis was among the best of his generation and one of the greatest economists of all time.

LEXICOGRAPHIC PREFERENCES

Once behavioral economists took seriously the limited information-processing capacity of the human brain (bounded rationality), they had to replace the neoclassical economic theory of consumer choice. The previous theory assumed additivity—the capacity to weight and add up all of the various features of all goods and thus rank and compare them to maximize utility within one's budget. Lexicographic preferences are consistent with bounded rationality. Economists conceive of a consumer having a manageable list of product characteristics organized ordinally, like an alphabetized dictionary. Consumers compare products with respect to the highest-ranked characteristic, and if one product is imagined better in that characteristic, the search stops and purchase ensues. If not, the consumer goes on to the next characteristic and repeats the procedure. This requires much less information processing than the additive model. It implies that other product features cannot compensate for failure to qualify on the first priority features. Price can be considered as just another product characteristic, and it may not be at the top of the list.

Theorists such as Peter Earl (1983) added uncertainty considerations to the basic conception without the computational requirements of attaching numerical probabilities to the satisfaction expected from consuming a product. A consumer may conceive of an acceptable gamble beyond which possible gains are not attractive.

Lexicographic preferences have implications for producers. Earl suggests that advertising should be aimed at changing consumers’ priority rankings rather than emphasizing their product’s strong points. If products are comparable with respect to high priority features, it may pay to introduce new product dimensions to meet emerging and created demands ahead of competitors. The theory lends itself to market surveys of yes-no questions rather than complicated sets of numerical tradeoffs.

In modern marketing, firms invest heavily in brand preeminence, perhaps hoping to displace any kind of characteristic comparison, simple or weighted. Further, firms search for how to create an image with which the
consumer personally identifies. An emotional trigger that forestalls comparison is the ultimate lexicographic process. People do not necessarily have either probable values attached to products or priority lists for all categories of purchases. Decisions to buy may be formed in the particular case and are description, context, and procedure dependent. Daniel Kahneman (1999) suggests that people imagine an answer to the subjective happiness question on the fly, instead of retrieving preferences from memory. Stores aim to create impulse purchases.

A complementary conception of choice conserving of mental energy involves allocating one's budget to broad categories of spending all within a total budget constraint. Once the categories are set, there may be little substitution of items from one budget to another. Further, there seems to be a class of products that are pursued initially regardless of cost.

Some economists consider the inability of lexicographic preferences to provide deterministic formal support for the theory of market equilibrium as a drawback, while others were never fascinated with theoretical equilibrium in the first place.

LIBERAL PARTY (BRITAIN)

The Liberal Party in Britain was formed in March 1988 as the Social and Liberal Democratic Party (SDP) when the Liberal Party merged with the Social Democratic Party. A vote in July 1989 finalized its new name as the Liberal Democrats. The two merging parties had merely strengthened the alliance between the two parties that had existed from 1981 and that had operated since that year under the dual leadership of David Steel (Liberal) and David Owen (SDP). In 1988 Owen refused to agree to the merger and Steel, although he led the Liberals into the merger, declined to lead the new party. The leadership of the new party fell to Paddy Ashdown who won a contest against Alan Beith, in July 1988. Ashdown now led a small struggling party whose position was thwarted by the fact that Owen continued to operate outside the merger with his short-lived continuing SDP, and Michael Meadowcroft, Liberal member of Parliament (MP) for Leeds West, refounded the by now minuscule Liberal Party. Nevertheless, since that period the Liberal Democrat leaders Ashdown, Charles Kennedy, and Ming Campbell have successfully revived the status of the Liberal Democrats, and indeed the old Liberal Party, to a level of political success not seen since the 1929 general election.

The revival of the Liberal Democrats began with a by-election victory at Eastbourne in October 1990, an event that contributed to the fall from office of Prime Minister Margaret Thatcher. It continued to secure victories in parliamentary by-elections and in municipal contests, although it won only twenty seats in the House of Commons in the 1992 general election, securing only 18 percent of the vote, an insufficient number to project it to major success under the first-past-the-post (winner takes all) British system of electing the House of Commons. Nevertheless, the Liberal Democrats have continued to grow in number and influence, largely on a mixture of Liberal policies, and have risen to approximately 60 members of Parliament (MPs).

Traditionally the Liberal Party has been committed to free trade but by the 1980s it was drifting toward the view that government might, under some circumstances, be justified in intervening in economic growth. It also supported the Conservative Party in Europe in 1993 by endorsing the Conservative government and the Maastricht Treaty in 1993. The Party supported the Labour Party under Prime Minister Tony Blair, following the general election of 1997, and particularly supported the Labour government’s moves toward devolution for both Scotland and Wales, the Celtic areas that the Liberal Democrats and the old Liberal Party had traditionally considered to be their strongholds. However, its distinctive demand for proportional representation in elections marks it off from the Conservative and Labour parties, who prefer to maintain the existing winner-takes-all strategy of British parliamentary politics. Although Blair set up a commission on changes in the voting system under Lord Roy Jenkins of Hillhead, LDP leader in the House
of Lords, to examine alternative political systems and to make recommendations, the Labour government has shown scant interest in any system that would undermine its massive parliamentary majorities secured under the winner-takes-all system. Nevertheless, the Liberal Democrats had an indication of what might be elected when the European elections of June 1999 were conducted on a basis of proportional representation. Under the winner-takes-all system used in 1994 they secured only two members of the European Parliament (MEPs) with 17 percent of the vote. In 1999 they secured ten MEPs with only 13 percent of the vote.

Although it attracts support from across the social divide, the Liberal Democrat Party tends to attract middle-class and professional people committed to the ongoing protection of individual rights but who are prepared to accept that the state has an important social role to fulfill. It is now no longer the party of big business as it was in the nineteenth century but more that of the small shopkeeper and the small businessperson. It also represents the interests of some of the old right-wing Labour voters who left the Labour Party in 1981 to form the SDP, and which finally flowed into the Liberal Democrats.

Despite its growth, the Liberal Democratic Party of today is a far less successful party than the old Liberal Party that emerged in the mid-nineteenth century, even though its policies are still largely in tune with the old Liberal Party. The Liberal Party is considered to have emerged at a meeting at Willis's Rooms in 1859 when the Whigs, Peelite Tories who opposed protectionism, and radicals met to serve under Lord Palmerston. The group was subsequently led by Lord John Russell and W. E. Gladstone, who firmly established Gladstonian Liberalism in his 1868–1874 and 1880–1885 ministries and drew considerable support from the nonconformist religions at this time. From the start the Liberal Party was committed to free trade, religious toleration, efficiency, and an international policy of promoting peace. Although the Nonconformist association has long gone, most of the other policies are reflected in the modern Liberal Democrats. The Liberal Party operated throughout the country in Liberal clubs organized into constituencies through local bodies that denoted their number: the Liberal Two Hundred or the Liberal Four Hundred. These groups were brought together and given a sense of unity by the formation of the National Liberal Federation in 1877.

Under Gladstone the Liberals split in 1886 on the issue of Home Rule for Ireland, the Home Rule supporters siding with Gladstone and the Unionists, who favored the continuation of the union with Ireland, moving with Joseph Chamberlain into the Conservative Party. Lord Rosebery, who succeeded Gladstone in 1894, pressed for issues such as temperance, strongly supported by the Nonconformists and the disestablishment of the Welsh Church. However, the divided party struggled until 1905 when it replaced the Conservatives and won a general election in 1906. This brought about a landslide Liberal victory, which sustained the Liberal Party in office until 1915 with the help of two further general elections in 1910. During these years the Liberals, greatly influenced by their parliamentary leader Henry Campbell-Bannerman, Prime Minister Herbert Asquith, and their Chancellor of the Exchequer, David Lloyd George, introduced the Liberal social reform of old-age pensions and national insurance, which were designed to alleviate poverty and avoid the need for a costly break-up of the New Poor Law. However, though these were remarkable developments, the Liberal Party found difficulty in prosecuting effectively World War I, which started in 1914, and Asquith formed a wartime coalition government in 1915. As a result when Asquith resigned as prime minister in 1916, perhaps with the expectation of being brought back, Lloyd George stepped into the breach. The result was a split within the Liberal Party, which was not officially healed until 1923. Even then the Liberal Party remained divided, and by the 1930s there was the Lloyd George group, the Samuel group, which was the old Liberal Party, and the Sir John Simon Liberals, who joined the Conservative Party. Long before this final split the Labour Party had replaced the Liberal Party as the progressive party of government in British politics. Over the next fifty years the Liberals declined as a party, with occasional revivals under Jo Grimond and Edward Thorpe as well as a brief period of a Lib-Lab Pact in 1977–1978. However, none of this brought the revival of the Liberal Party back to the position of being a party of government, and even under the modern Liberal Democratic Party the prospects of forming a government remain extremely remote.

LIBERALISM

Liberalism has been conceived of as at once a political philosophy, as an allied political movement, and as a way of thinking about the foundations and practices of government. Liberalism has historically been defined by a great diversity of ideas, largely due to the changing contexts within which and against which liberal thought has taken shape. Despite this diversity, there are a number of basic premises common to all liberal traditions. The most central of these is a valorization of the individual and of individual liberty, and much liberal debate has concerned the conceptions of human nature that undergird these terms. Linked to this, liberal thought has been preoccupied with how individuals should govern and be governed with the least possible intervention or coercion. While liberalism arose simultaneously with the Enlightenment as an often revolutionary response to religious and absolutist forms of government, liberal democracy has, in the aftermath of the Cold War, become the dominant form of government.

HISTORY

While the term liberal was not commonly used until the mid-nineteenth century, much liberal thought traces its origins to early modern writing, and in particular to John Locke's (1632–1704) writings on natural law in the context of the Glorious Revolution of 1688. Against the doctrine of the divine right of kings, Locke (1690) argued that individuals are God's property and as such have a natural right to the means of survival—life, health, liberty, and property. The social contract is not, as it was in Thomas Hobbes (1588–1679), necessitated by fear, but rather secures the protection of the natural rights that individuals enjoyed in the state of nature. Locke's most lasting contributions to liberal theorizing were his conception of civil society as a society of free men, equal under the rule of law, and the link he drew between liberty and property. Locke's thought and in particular the emphasis he placed on consensual government would become central in the formulation of the American Declaration of Independence and the U.S. Constitution.

With the eighteenth-century Scottish Enlightenment and the rise of free market capitalism, liberal thought came to entail a more encompassing framework, including most importantly an economic theory. Against mercantilism, Adam Smith (1723–1790) argued in The Wealth of Nations (1776) that a free market economy, if left to its own devices, would automatically regulate itself through an "invisible hand." Smith viewed human nature as inherently propelled by self-interest that is, however, softened by the capacity for "sympathy." Through the process of competition, individuals would fulfill their self-interest and, in the process, produce a balanced society. On the European continent, the Enlightenment tradition was defined by a much more rationalist conception of human nature that centered on the individual ability to reason and to direct change. The conceptions of individual reason and limited government in the work of Immanuel Kant (1724–1804) and Wilhelm von Humboldt (1767–1835) in Germany and Voltaire (1694–1778) and the Marquis de Condorcet (1743–1794) in the context of the French Revolution (1789–1799) had a lasting influence on liberal thought.

In the nineteenth century, English liberal thought developed an increasingly rationalistic turn. Starting with the utilitarianism of Jeremy Bentham (1748–1832) and James Mill (1773–1836), increasing trust is placed in the human capacity for reason and for the rational design of social institutions. The principle of utility, which in Adam Smith was reduced to individual calculations unknowable to the sovereign, now becomes the basis of governing society as a whole. Human action, argue the utilitarians, needs to be judged according to whether it promotes the greatest happiness for the greatest number of people. John Stuart Mill (1806–1873), while placing himself within the utilitarian tradition, argued that representative democracy was the best system to ensure that everyone had the freedom to pursue his own conception of happiness. In his most seminal contribution to liberal thought, On Liberty (1859) 1989, Mill sought to fuse his father's utilitarianism with a strong defense of individuality and personal autonomy. His argument hinged on the idea of character and "self-development" based on a notion of human nature as perfectible. By extension, however, Mill's argument allowed for gradations of democracy based on the principles of civilization and progress that, especially in the colonies, entailed the justification of despotism (Mehta 1999).

In the early twentieth century, in the context of the crisis of the free market regime and the rise of socialism, a more state-centered strand of liberalism developed in Britain that sought to balance individual freedoms with equality in the form of welfare provisions. Elaborated in the work of sociologist Leonard Hobhouse (1864–1929) and later supported by the economic theories of John Maynard Keynes (1883–1946), the "new liberalism" was central to the development of the welfare state. In the aftermath of World War II (1939–1945) and in the context of the Cold War, a liberal conception and critique of totalitarianism arose in the work of Karl Popper (1902–1994) and in Isaiah Berlin's (1909–1997) conception and valuation of negative liberty (freedom from) over positive liberty (freedom to). For much of the century, however, welfare-state liberalism remained hegemonic in liberal thought and politics.

However, in the context of the crisis of the 1970s and rising critiques of the welfare state, liberal debate on the
role of the state was reinvigorated. Arguing against the aggregating postulates of utilitarianism, John Rawls's (1921–2002) *A Theory of Justice* (1971) proposes a neo-Kantian, rights-based conception of “justice as fairness.” Against a teleological conception of the good, this contractarian approach is premised on a heuristic device Rawls terms the “original position” in which individuals are imagined to be behind a “veil of ignorance” about their potential standing and attachments within society. From this position of distance and ignorance, individuals will rationally decide on a generalizable principle of justice. Importantly, this conception enables Rawls to move away from making any substantive claims about the public good or liberal society, to instead propose a proceduralist conception of justice based on rights rather than any particular version of the good. Partly as a response to this critics, Rawls (1993) later proposed the concept of political liberalism. Here, the question of pluralism is addressed by reducing the conception of justice to the idea of public reason defined by an “overlapping consensus.” According to Rawls, this revised conception is necessitated in order to guarantee the stability of society in the context of diverging conceptions of the good.

In a 1974 critique of *A Theory of Justice*, Robert Nozick (1938–2002) proposes a minimal state, responsible primarily for the protection of private property. Friedrich von Hayek (1899–1992), who had throughout the period of welfare-state liberalism argued against state intervention into the economy, became one of the most influential proponents of a return to classical liberalism. Drawing on the Scottish Enlightenment tradition, Hayek proposed that society and in particular the economic sphere were unknowable to policymakers and would be governed by a “spontaneous order” as long as state intervention would be reduced to sustaining a peaceful order. Hayek’s theorization of the limits of state reason became one of the most influential tracts in the rise of neoliberalism in the last decades of the twentieth century.

LIBERALISM AND ITS CRITICS

Critiques of liberalism have usually converged on liberalism’s disembodied conception of the individual. Edmund Burke’s (1729–1797) writing on the French Revolution ([1790] 2001) lay the groundwork for the conservative critique of liberalism. Burke posited the organic nature of traditions evolved over time against what he perceived to be the ephemeral and dangerous rationalism of the Enlightenment. More recently and in explicit response to John Rawls, what has come to be known as the communitarian critique faults liberalism on both an ontological and a normative basis. The individual, communitarians like Michael Sandel (1984) argue, is not presocial; rather, the individual only emerges through and within social and communal relations. Secondly, a society of atomized individuals is undesirable, since it removes the individual from the relations through which life becomes intelligible (MacIntyre 1981) and morally meaningful (Taylor 1979).

In his critique of liberal conceptions of freedom, Karl Marx (1818–1883) argued that the political emancipation of the individual is enabled by removing all difference from the political to the private realm. The liberal conception of autonomy is thus fictitious in that an individual’s socioeconomic and religious particularities continue to exist outside liberalism’s purview. Later, and here more explicitly linking liberalism to the rise of capitalism, Marx showed the ambiguities of liberal emancipation, famously suggesting that capitalism freed workers to sell their labor-power in the market place and simultaneously “freed” them from the means of production.

Similarly concerned with the constitution of the individual, Michel Foucault (1926–1984) viewed liberalism as a political rationality, as a practical way of thinking about the modalities and targets of government. Liberalism entails both the critique of previous ways of governing and the rise of new modalities of power that seek to produce a citizenry capable of self-government. Processes of responsibilization, disciplining, and normalization are thus not antithetical to liberalism, but rather the condition for liberal forms of rule. Liberal freedom is here not conceived of as the gradual removal of state intervention, but as entailing a new regime of power and a new approach to how one should govern oneself and others.

Liberalization, Trade

In 1960 less than one-sixth of the countries in the world had open trade policies. Most countries had various types of trade restrictions such as high tariff rates (taxes on imports) and extensive nontariff barriers (such as quotas that restricted the physical quantity of specific imports allowed into a country). In addition, the official exchange rate often exceeded the black-market exchange rate, and governments exercised monopoly controls on exports and other trade-related matters. Yet by 2000 three-quarters of the countries in the world had removed many of these impediments and were now open to international trade. This is a remarkable transformation and highlights the importance of trade liberalization in the global economy.

What precipitated the extensive trade liberalization that occurred? Much of the credit is usually given to the sixty years of multilateral trade negotiations that has resulted in ever-lower trade barriers under the auspices of the General Agreement on Tariffs and Trade (GATT). Since GATT’s inception in 1947, manufacturing tariffs in industrialized countries have fallen from 40 percent to 4 percent, and world trade has increased eighteenfold. Initial GATT membership of 23 countries expanded to 148 countries and the trade rounds became the international forum in which member governments agreed on rules for the conduct of international trade. The multilateral trade agreements involved nondiscriminatory tariff reductions so that all countries benefited—the “most favored nation” clause—and the tariff cuts were “binding” and could not be restored at a later date.

Countries would not have agreed to lower levels of import protection unless there were good arguments in their favor. Trade liberalization allows countries to specialize production and export in their areas of relative strength and to import products that other countries can make at lower cost. It enables access to a wider range of products, and access to foreign products helps diffuse innovations and new technologies. Openness to trade provides additional competition that can spur local firms to greater efficiency and keeps domestic prices low.

In the context of developing countries, a series of country studies sponsored by the World Bank, the Organization for Economic Cooperation and Development (OECD), and the National Bureau of Economic Research demonstrated that trade barriers imposed significant costs, whereas trade openness appeared to be associated with improved economic performance, although the underlying empirical research has not gone unquestioned (Rodrik 1999). For these countries, import substitution using high effective rates of protection had been the dominant vehicle by which industrialization has proceeded. Initially, local suppliers would have to be nurtured and protected from the competitive pressures applied by long-established foreign producers. Over time, domestic inefficiencies would decline as these “infants” learned from experience and were able to reduce costs of production. The end result would be a far more diversified and self-reliant industrial structure less dependent on the vagaries of international commodity prices. In the 1970s increasing disenchantment with this strategy emerged, and an alternative approach, identified as outward- (or export-) oriented and associated with East...
Asian development, became more popular and trade barriers fell (Edwards 1993).

While trade barriers in manufacturing have fallen extensively, the trade liberalization agenda has expanded its scope and consequently run into considerable difficulties. In 1995 GATT’s successor, the World Trade Organization (WTO), became operational. Whereas GATT focused on trade in goods, the WTO concentrates on trade in services, intellectual property, and agricultural subsidies. According to the OECD, rich countries spend $280 billion a year on agricultural producer support; agricultural price support amounts to 20 percent in the United States, 50 percent in Europe, and 80 percent in Japan. These agricultural subsidies are trade-distorting, encouraging supported farmers to produce more, and this in turn lowers world prices and hurts farmers in poor countries that have a comparative advantage in the production of these subsidized commodities. Poor countries want agricultural liberalization in rich countries, yet there has been little progress in persuading richer countries to dispense with these subsidies. This leads credence to the claims about unfairness in trade negotiations made by Kevin Watkins and Penny Fowler in *Rigged Rules and Double Standards* (2003).

Trade in services, especially related to issues of labor mobility across national boundaries, and TRIPs (trade-related aspects of intellectual property rights), which are of special interest to the pharmaceutical and software industries, are equally contentious issues. The latter is related to the manufacture of generic drugs and their sales to poor countries. Claims for “fair trade” rather than “free trade” cloud trade negotiations even further, because non-government organizations have been advocating “social clauses” in trade liberalization agreements relating to child labor, human rights, the environment, wages, and conditions. Their position is that trade sanctions should be imposed against countries that do not meet international standards in these areas.

Given these stumbling blocks and complications, it is not surprising that there has been a move away from multilateral forums to negotiated bilateral or regional trade agreements outside the WTO framework. More than 300 such preferential trade agreements exist as of 2007. Whether these agreements assist global trade liberalization or hinder the process is not clear (Bhagwati 2002).

Trade liberalization is only part of a broader globalization movement and it needs to be carefully sequenced with other policy reforms. In general, trade liberalization should precede financial liberalization, domestic financial liberalization should precede external financial liberalization, and direct investment liberalization should precede portfolio and bank loan liberalization (capital account liberalization). Free inflows of foreign financial capital should only be allowed at the tail end of a liberalization program, and controls on suddenly increased inflows of short-term capital may be warranted. The purpose of these controls is to quarantine economies from excessive “hot” money inflows and outflows that disrupt economic stability and lead to exchange rate misalignments.

Overall, the welfare effects of trade liberalizations fall within the realm of second-best economics. There is still dispute about the direction of causation in the association between openness to trade and East Asia’s rapid growth. What role have trade liberalization packages played in the performance of outward-oriented economies? A number of these countries, such as Japan, Korea, Singapore, and Taiwan, have promoted exports, but in an environment where imports had not been fully liberalized. The success of the East Asian countries with export-led growth suggests that some selectively determined degree of government intervention played a key role. Imports and lower tariffs may stimulate productivity, but import competition may have little impact on productivity growth if the domestic producers are technologically backward: Benefits accrue only to domestic producers that are roughly comparable to their foreign counterparts. This, then, suggests a role for trade-adjustment packages and safety nets for those disadvantaged by trade liberalization.

**LIBERATION**

*Liberation* entered the English language during the fifteenth century. In modern terms liberation has taken on a political meaning to describe a condition of being free from impediments and more particularly activities leading toward the removal of restrictions to free action by a group or a person defined by nationality, race, gender, sex-
Liberation

Liberation from Slavery

The abolitionist movement sought to end the practice of slavery on a global scale by ending the slave trade and emancipating slaves held in bondage. The Emancipation Proclamation (1863) issued by Abraham Lincoln (1809–1865), for example, declares that all slaves in Confederate territory were to be “freed.” The act of emancipation also allowed slave owners to set their slaves free. The Haitian slave revolt (1791) against French slavery, led by Toussaint Louverture (1743–1803) on the island of Saint Domingue, heralded briefly the first free black republic. The slaves in Saint Domingue drew on the Declaration of the Rights of Man, adopted by the leaders of the French Revolution in 1789, to demand liberation from the bondage of slavery, allowing them to be considered free and equal human beings, a right denied to subjects in French colonies. Initially the demand of the slaves in Saint Domingue was to be freed from slavery in order to be part of the French Empire as free people. Later in the revolt, as pointed out by C. L. R. James (1901–1989) in The Black Jacobins (1938), this changed to a demand for independence after the refusal of France under the rule of Napoléon Bonaparte (1769–1821) to grant the slaves “the rights of man.”

Colonialism and National Liberation

While the expansive empires of the Romans, the Ottomans, and the Greeks possessed what might be considered colonies, it was after the sixteenth century that colonialism took on its modern meaning and eventually led to national liberation struggles. Developments in navigation and the technologies of war along with the changing patterns of trade facilitated the expansion and intensification of colonial rule and settlement by European powers over the rest of the world. Colonialism therefore meant ruling over another territory and its peoples either indirectly, through local elites like chiefs, or directly where there was a settler population, as in Australia and large parts of Africa and Asia.

The existence of empires that controlled large swaths of territory from a remote center of political power was challenged by the emergence of self-determination and nationalism. These principles held that states and groups of people who shared an affinity had the right to rule over themselves. The right to self-determination came into conflict with the maintenance and possession of colonies. This dilemma led to a protracted debate among prominent European philosophers of liberal thought, including John Stuart Mill (1806–1873) and Alexis de Tocqueville (1805–1859). Some argued that “states,” following the Treaty of Westphalia (1648), should observe the principle of self-determination and, where states existed, this principle should be upheld to preserve territorial integrity. However, this principle did not necessarily apply to “peoples.”

Benedict Anderson has argued that as a sensibility, nationalism emerged first in the Latin American colonies among the Creole elites. While “nations” may define themselves based on the subjective sense of a shared language, culture, or history, Anderson argued that nations are “imagined political communities” (Anderson 1991, p. 6). As a political idea, it holds that a “people,” however defined, have the right to self-government, self-rule, or self-determination, and this principle was formally adopted by the United Nations in 1960 with the Declaration on the Granting of Independence to Colonial Countries and Peoples. A “people,” defined as such, could legitimately claim the right to independence, but this idea was not universally accepted, and the struggle to realize independence was taken up by a range of national liberation movements in Africa, Asia, and the Americas. In these movements liberation was used to refer to the right of peoples to rule themselves, free from foreign domination by an external occupying power, and to live under an independent political authority. The methods used to achieve the aims of liberation by these movements took various forms, from nonviolent political agitation, as exemplified by Mahatma Gandhi’s (1869–1948) idea of satyagraha to end British control over India, to the use of force and guerrilla warfare, as in the cases of Cuba from Spain, Algeria from France, Angola from Portugal, Zimbabwe from Britain, East Timor from Indonesia, Tamil nationalists in Sri Lanka, and Palestine from Israeli occupation.

Racial Oppression, Discrimination, and Liberation

The expansion of imperial rule, from which modern colonial rule emerged, was also facilitated by the notion of
“race” as understood by Count de Gobineau (1816–1882), a French diplomat and writer who categorized humans as belonging to and originating from different “racial stocks.” It was believed that races had different strengths, capabilities, and weaknesses and that some races should be socially nurtured while others could be destroyed. Europeans of an Aryan stock were placed at the acme of the pyramid in Gobineau’s typology. This “scientific racism” contributed to the practice of colonialism and also fostered forms of social discrimination against particular groups of people within states, such as Jews in Germany and Poland, the descendants of free slaves in the United States, and black South Africans. On this basis therefore various forms of racism took root and fostered relations of hierarchy and domination between states and within states.

Racial discrimination led to another sense in which liberation came to refer to the struggle to free societies and individuals from racist institutional practices and racist thinking. The civil rights movement in the United States, led by African Americans such as Dr. Martin Luther King Jr. (1929–1968), demanded an end to the practice of segregation of Americans of African descent in southern states. The American civil rights movement also demanded representation in the democratic political system through the vote. Racism, in the institutionalized form that was practiced in South Africa, led to the demand for liberation from the severe effects of social, economic, and spatial separation of people on the basis of race, a situation formalized as apartheid after 1948 with the coming to power of the Afrikaner Nationalist Party.

While institutionalized racism has been successfully challenged by liberation movements, with African Americans now having the vote and South Africa inaugurating a nonracial democracy in 1994 under the presidency of Nelson Mandela, some argue that the more enduring psychological aspects of racism’s legacy continue to require a form of liberation. The Martinican-born psychiatrist Frantz Fanon (1925–1961) wrote in *Black Skin, White Masks* (1967) of the mental effects of racism on human beings, who need “mental liberation” to free the mind from racist ways of thinking about the self and others. Applying Fanon’s insights to academic knowledge, Edward Said (1935–2003), an American literary theorist of Palestinian descent, showed how racist assumptions underpinned many European understandings of the “Orient” and continue to operate in the academy with negative political effects. Also influenced by Fanon, the South African political leader Steve Biko (1946–1977), who was killed in police custody, emphasized the need for black South Africans to liberate their minds from the acceptance of racism by developing a “black consciousness.”

**CLASS STRUGGLE AND THE LIBERATION OF THE WORKING CLASS**

Liberation from racism and slavery has largely been based on the liberal premise that people are entitled to individual rights. Marxists, however, have argued that capitalist societies are also based on relations of exploitation defined by economic class distinctions between groups. For Karl Marx (1818–1883), liberation entailed freeing the working class from wage labor or “wage slavery,” which kept workers dependent on their bosses for their material reproduction. Liberation, Marx and Friederich Engels (1820–1895) noted in *The German Ideology* (1846), was therefore a process that required the material reorganization of society through the rearranging of the economic relations of production, thereby creating a classless society: “People cannot be liberated as long as they are unable to obtain food and drink, housing and clothing in adequate quality and quantity” (Marx and Engels [1846] 1967, p. 437). Marxism has inspired significant political liberation movements, notably the Russian Revolution of 1917, which provided the most influential alternative model of liberation to the liberalism of the West after World War II (1939–1945) until the collapse of the Soviet Union in 1990.

**GENDER, SEXUALITY, AND THE FREEDOM TO CHOOSE**

Since the nineteenth century the term liberation has also been used in defining movements that advocate changes in attitudes toward gender and sexuality (Wollstonecraft [1792] 1993). The American journalist Gloria Steinem declared 1970 “the year of women’s liberation.” “Women’s lib,” or feminism, as this movement has come to be known, refers to a diverse range of movements and philosophies that share the idea that gender should not be the primary determinant of an individual’s economic or sociopolitical rights, obligations, or opportunities. Women’s liberation has involved demanding for women the rights to vote in a democracy, to receive the same pay as men, and to exercise choices over their own bodies. Women, proponents argue, need to be liberated from the strictures of a male-dominated or patriarchal society. This liberation applies not only to women but to the gendered roles that men and women are socialized into performing, which reinforce patterns of inequality and discrimination. This notion is distinct from the use of liberation to redefine sexual relations in society. Such movements advocate an end to discrimination based on sexual orientation. The gay and lesbian movements, for example, advocate a redefinition of marriage to include same-sex couples. Such marriages are now recognized as legal in some countries, but it remains an ongoing liberation struggle.

LIBERATION MOVEMENTS

A liberation movement is a type of social movement that seeks territorial independence or enhanced political or cultural autonomy (or rights of various types) within an existing nation-state for a particular national, ethnic, or racial group. The term has also been extended to or adopted by other types of groups (e.g., women and gays and lesbians) that seek to free themselves from various forms of domination and discrimination. National liberation movements have been an especially important force in the modern world, and scholars have been interested in explaining their origins, strategies, and impacts. The division of the globe into nation-states, many of the wars among these states, and the hundreds of historical and contemporary conflicts among states and ethnic groups—in short, fundamental aspects of the modern world—cannot be understood without also understanding liberation movements.

TWO TYPES OF LIBERATION MOVEMENTS

Some national liberation movements are based on identification with and loyalty to a population and “its” state (or prospective state), regardless of the ethnic or racial composition of this population. The national feeling and identity underlying such movements is sometimes called “civic nationalism.” For example, the leading liberation organization in South Africa, the African National Congress (ANC), has long advocated a policy of “nonracialism” (in
effect, multiracialism), maintaining that South Africa belongs to all people who live there, whatever their race or tribe. Nationalism in the United States is also generally understood as civic in nature, although ethnic and especially racial nationalism (white and black) has often competed with this understanding.

In fact many liberation movements are based on identification with and loyalty to a specific ethnic or racial group that may or may not live within the jurisdiction of a single state. In fact bringing all co-ethnics within a single nation-state, through territorial expansion if need be, has been the aim of a number of nationalist movements. This type of national identity is often called “ethnic nationalism.” For example, the Zionist movement that founded the state of Israel may be understood as a type of ethnic (specifically, Jewish) nationalism. Similarly the Palestinian liberation movement, which has long been at odds with Zionism, is also mainly an ethnonationalist liberation movement—although a very small number of Israelis and Palestinians support the creation of a single “binational” state for both Jews and Palestinians that would incorporate Israel, the West Bank, and Gaza (i.e., historical Palestine).

The word liberation, originally meaning “setting free or releasing from,” first entered the English language in the fifteenth century. The term was not widely used in a political sense until the mid-nineteenth century and especially the mid-twentieth century. National liberation movements can, however, be traced back to the late eighteenth century. The temporal and geographic span of such movements—ranging from the North and South American wars of independence in the late eighteenth and early nineteenth centuries to the related (but distinct) European nation-building processes of the mid- and late nineteenth century and continuing through the decolonization struggles in Asia and Africa in the mid-twentieth century and beyond—raises the question of just how similar these movements actually are. Yet despite the wide variation among national liberation movements in terms of historical context, social base, strategies, and specific aims, a common thread uniting them all has been the need to contend, whether as friend or foe, with the nation-building projects that have been so central to the modern world.

The modern nation-state, along with the movements seeking to bring this form of political and social life into existence—whether through intellectual argument, cultural imagining, or force of arms—has been a contradictory social phenomenon. Objectively the political form of the nation-state is thoroughly modern, having come into wide existence only within the last 200 years or so, as well as highly contingent, with the ability of any given national liberation movement to achieve its objective of nationhood dependent upon a host of historical variables. Yet subjectively the nation or “the people,” despite (or perhaps because of) its existence as what Benedict Anderson (1991) calls an “imagined community,” is necessarily understood as natural, eternal, and as unchanging as the sun. The two core elements of national liberation movements—the political task of obtaining state power (whether through seizure or creation) and the cultural process of constructing a “nation”—have therefore frequently coexisted uneasily. The efforts of artists, intellectuals, and political leaders in the vanguard of national liberation struggles—along with the mass movements they have sought (with varying success) to inspire—have been aimed at the creation of a nation-state that, by definition, did not yet exist; yet this struggle has been represented as the natural unfolding of an inevitable, historically preordained process.

The concept of democracy, the idea (and ideal) that the state should represent the interests of the nation or the people, has provided an important ideological justification for attempts to bring together the cultural and political dimensions of the nation-state form. Yet the inclusive, revolutionary-democratic equation of state, nation, and people, ushered into the modern era most powerfully by the French Revolution, has existed alongside the exclusionary practices of modern bureaucratic states, including the “purification” and standardization of a single national language, mass education aimed at spreading this language and an attendant national feeling, and even occasionally the mass expulsion or genocidal elimination of those unfortunates who do not belong to the “right” national or ethnic (including religious or linguistic) group—all in the quest to create an ethnically homogeneous nation. Many national liberation movements, moreover, have ignored or even actively suppressed social antagonisms based on class and gender, for example, that would allegedly weaken national identity. Thus the “liberation” these movements have sought has typically been partial at best.

The nation-state has existed throughout its relatively brief history in a complex relationship with another great force that has shaped the modern world—capitalism. Although nineteenth-century liberal economic doctrine extolled the benefits of free trade, the rise of industrial capitalism in Europe was closely linked to mercantilism and state-led “national economies,” a fact that “no economist of even the most extreme liberal persuasion could overlook,” as E. J. Hobsbawm (1992, p. 28) notes. Anderson’s (1991) argument that “print-capitalism” fueled the rise of the mass-circulating newspapers and books upon which the “imagined community” of the nation arose shows that the relationship between capitalism and the nation-state was cultural as well as economic. Furthermore the decolonization struggles of the
post–World War II (1939–1945) era must of course be understood in relation to the dynamics of capitalist imperialism. Hobsbawm (1992) points out the close links forged in at least some anti-imperialist national liberation movements between the goals of political independence and social revolution. At the dawn of the twenty-first century—amid neoliberal celebrations of the weakening of state regulation of the economy (seen as the final unfettering of the free market), unprecedented worldwide flows of capital, people, and goods, and a resurgence of nationalist feeling—debate rages as to whether the nation-state form can survive capitalism’s global expansion. Many analysts, especially Marxists, have long predicted that global capitalism would undermine “parochial” nationalist sentiments—though this seems no closer to realization than it was at the beginning of the twentieth century.

THE ORIGINS OF LIBERATION MOVEMENTS

What causes liberation movements? Why do they arise when and where they do? Clearly national or ethnic identity and solidarity alone do not automatically produce social movements, and to some extent national identity is itself a product of nationalist mobilization. Furthermore, while nationalism may help to facilitate capitalist economic activities—by encouraging a common language, for example, or by weakening potentially disruptive class identities—its functionality for capitalism does not explain the origins of national identity or nationalist movements in the first place.

Many scholars would argue that liberation movements arise for the same reasons any social movement emerges: widespread grievances, plus a preexisting collective identity (in this case, a widespread national or ethnic identity), plus some significant formal or informal organization or social ties among this self-identified population, plus a sense of political empowerment or efficacy, plus a political context that facilitates (or at least is not inimical to) collective action. As noted, however, national or ethnic identities may be more of an outcome than the initial cause of liberation movements. That is, liberation movements may initially focus on very specific grievances and only gradually address more general grievances and evolve into movements claiming to represent the aspirations of a national or ethnic group as such. During and after the transformation of such movements into national or ethnic movements, they typically help spread a sense of national or ethnic identity to growing numbers of people. Nationalist identities and movements, in short, typically evolve contemporaneously.

Some scholars have also proposed specific theories of nationalist or ethnic mobilization. These theories tend to focus on the political and social conditions that encourage specifically ethnic or national identities—as opposed especially to class identities—and that generate widespread grievances among ethnic and national groups. In one view, those socially and territorially segregated ethnic groups that come into economic or military competition with one another are especially likely to develop strong ethnic identities and to mobilize in collective self-defense. The wealthier and more powerful group may mobilize in reaction to a perceived threat, and the poorer and less powerful group may mobilize so as to improve its own collective interests. Paradoxically, competition may be especially fierce if the two communities are or become more nearly equal. This competition (and concomitant nationalist mobilization) may gradually erode to the extent that the two populations become socially integrated (through voluntary association, for example, or intermarriage), but it is likely to persist if the two groups remain “socially distant” from one another.

The political exclusion and domination of particular ethnic groups, on an explicitly ethnic basis, is also likely to encourage ethnonationalist identities and movements for political rights. Overseas imperialism in its colonial form strongly encouraged the formation of national identities and liberation movements even among groups that did not previously consider themselves members of the same group (the boundaries of colonies were typically established with little regard for the ethnic composition of the local populations). Identities such as “Indonesian” and “Mozambican”—let alone liberation movements based on these identities—did not exist prior to the creation of colonial states.

The strategies of liberation movements have generally been shaped by their organizational strength as well as by the responses of authorities (Irvin 1999). Some authorities have seen political advantages to extending rights to liberation movements or even granting territorial independence in colonial situations. Not surprisingly, authorities have been more accommodating to narrowly political movements, dominated by economic elites, that do not challenge the economic well-being of these authorities and their constituents. By contrast, authorities have strongly and usually violently resisted liberation movements that represent a threat to their economic interests, and such resistance has generally induced liberation movements to adopt more coercive strategies of their own, including forms of armed struggle such as guerrilla warfare and terrorism—the latter strategy especially common in colonies with large settler populations.

THE FUTURE OF LIBERATION MOVEMENTS

In an age of increasing globalization, some have suggested that the relative importance of nation-states is declining,
as states find it increasingly difficult to control the movements of labor, commodities, and especially capital. In this view, the advantages of creating or controlling states (or subnational political units) are rapidly decreasing. And yet there are numerous instances of ongoing national liberation and ethnonational movements around the world. These movements have a range of goals—from national independence to regional autonomy—as well as varied social bases—from immiserated Palestinians in the West Bank and Gaza to wealthy elites in the Santa Cruz region of Bolivia. A short list of early twenty-first-century liberation struggles includes Irish nationalists in North Ireland, Tamils in Sri Lanka, Tibetans in China, Palestinians in the West Bank and Gaza, Kurds in Iraq and Turkey, Kashmiris in India, Muslims in southern Thailand, Chechens in Russia, Quebecois in Canada, Basques in Spain, Zapatistas and other indigenous groups in Mexico, Albanians in Yugoslavia (Kosovo), Acehnese in Indonesia, several ethnic groups in the northeastern states of India (including Nagaland and Tripura), and many others. Despite the enormous variety and complexity of such conflicts, their sheer number indicates that ethnonational and national liberation movements will remain extremely important for the foreseeable future.

**LIBERATION THEOLOGY**

Liberation theology, or theology of liberation, is among the movements for social change that emerged in the Americas in the 1960s. Born within Christian churches, it upholds an understanding of the Christian faith as demanding an “option for the poor,” that is, a continuous commitment to the self-liberation of the oppressed. From its inception, it has had important ties with grassroots organizations and actions for social change—siding with the victims of socioeconomic oppression and of political and military repression.

Since early on liberation theology attracted the attention of social scientists and policymakers, as its effects both belied scholarly assumptions—for example, religion having a decreasing influence and a predominantly conservative function in the larger society—and raised fears of grassroots opposition to capitalism among the economic, political, and military elites north and south of the Rio Grande.

**ROOTS AND DEVELOPMENT**

Several factors influenced the emergence of liberation theology. The growing resistance throughout the Americas in the 1960s to economic exploitation, political repression, and official complicity with both is indeed among these. This resistance, partially inspired by the Cuban Revolution (1959), found mounting echoes among urban youth, the poor, students, and intellectuals—including a rising number of church activists and thinkers. These stimulated attempts (including a “theology of revolution,” “Christian left,” and Christian “communitarianism”) to ground the struggle against exploitation and repression in the biblical tradition, especially in Jesus’s actions, words, death, and resurrection—and thus to disprove the claim (shared both by Christian capitalists and Marxist atheists) that the churches’ social role could only be a conservative one. Following suit, churches started not only initiatives for economic development and respect of human rights, but also theological foundations for such initiatives. The Second Vatican Council (1962–1965), the social encyclicals of Popes John XXIII (1963) and Paul VI (1967), as well as the 1968 Second General Conference of Latin
American Roman Catholic Bishops, were all particularly influential in that change of direction—particularly through their explicit Christian affirmation of the divine right of all peoples to govern themselves democratically, and to have access to the material goods necessary to satisfy their basic material needs, even through revolutionary social, economic, and political change, if necessary. On the Protestant side, the World Conference on Church and Society in Geneva, sponsored by the World Council of Churches (1966), a follow-up Consultation on Church and Society in Sao Paulo, Brazil, sponsored by a provisional commission for the Unity of Latin American Evangelicals (1967), and the Third Latin American Evangelical Conference (Buenos Aires, 1969), all contributed to Protestant Christians’ embracing movements for social justice. In both Protestant and Catholic quarters, a growing chorus of voices, official and otherwise, affirmed much more clearly from the 1960s on than in earlier times the Christian obligation to fight for socioeconomic justice, political democracy, human rights, and world peace, especially in defense of the poorer populations. Entwined with these, in the United States, the civil rights movement, the Black Power movement, the antiwar movement, the United Farm Workers movement, the women’s movement, and the American Indian liberation movement, all contributed to the emergence of a rich diversity of theological reflections from the late 1960s on.

A first digest of some key ideas of a liberation theology, as well as a first Spanish use of the idiom itself, *teología de la liberación*, appeared in the lecture “Hacia una teología de la liberación” (Toward a theology of liberation), delivered in 1968 to a clergy meeting in his native Peru by Roman Catholic priest Gustavo Gutierrez (b. 1923), dubbed “the father of liberation theology” since. About the same time, the former Brazilian Presbyterian pastor Rubem Alves (b. 1933), exiled in Princeton Theological Seminary, used the expression in his dissertation *Towards a Theology of Liberation*, with ideas converging with Gutierrez’s. In 1969 the African Methodist Episcopal minister/theologian James H. Cone independently finished his book *A Black Theology of Liberation*, the cornerstone of black liberation theology—deeply inspired by the revolutionary call of the Black Power movement for the black population in the United States to take in its own hands the task of achieving equality, autonomy, and respect “by any means necessary,” as well as by its criticism of the complicity of churches and theologians with white supremacy.

Throughout the 1970s and 1980s, the movement grew in numbers, visibility, and influence across the churches in the Americas. In response, military dictatorships—in at least ten countries of the Caribbean, Central America, and South America—unleashed violent repression against those linked to liberation theology. Among the hundreds of thousands of lives thus lost, Msgr. Oscar Arnulfo Romero, archbishop of San Salvador, murdered while celebrating mass in a hospital chapel in 1980, was the most remarkable victim of that backlash, becoming a popular saint-martyr symbolizing the Christian commitment to the liberation of the poor. That year, a document outlining the inter-American strategy of the Reagan administration stated: “U.S. foreign policy must begin to counter (not react against) liberation theology as it is utilized in Latin America by the ‘liberation theology’ clergy” (Committee of Santa Fe 1980).

The military repression; the stifling of dissent in Roman Catholicism under Pope John Paul II (1978–2005), with parallel processes in many Protestant churches; the accelerating impoverishment of Latin American peoples under the new global economy; the emergence of fragile democracies in the wake of most military dictatorships; and the growing appeal of Pentecostalism among the Latin American poor stunned and beset liberation theology through the last two decades of the twentieth century.

**KEY IDEAS, DEBATES, AND REPERCUSSIONS**

For liberation theology God is the God of the poor. God’s self-revelation is first and foremost in, to, and through the poor—not least in the incarnation, birth, words, deeds, persecution, torture, execution, and resurrection of Jesus, as expressed, among others, in Matthew 25: 31–46. Modern poverty is not a result of accidental scarcity (as it might have been in other times and places), but of systemic exploitation by the few at the expense of the many. Poverty is the result of the sin of the powerful, not of the poor: the product of a free human rejection of God’s call for caring for the poor and oppressed. Salvation is, therefore, inseparable from the radical embracing of God’s option for the poor, and thus entailing, among others, a call against capitalist exploitation.

The theology of liberation has often been charged with reducing Jesus to a social revolutionary. Albeit the charge could be deemed unfair, the fact is that such an iconic image was quite pervasive during the first two decades of the history of the movement—more among some “followers” than amid the theologians in the movement proper. As the years went by, such images became less recurrent. As in any emerging movement fighting for deep structural change, liberation theology developed much more what distinguished it from conservative, dominant theologies, than what both might hold in common. Thus, an emphasis on the historical Jesus, on the human facet of the divine incarnation, and on the social dimensions of the life, message, passion, death, and resurrection of the Christ, have been critical in liberation theology. The image of Jesus in this theology is and has been that of...
someone essentially identified with “the least among us,” whose entire life was (is, and will continue to be) radically revolutionary—and not just marginally or accidentally—and thoroughly world-shattering in terms economical, social, political, ethnic, linguistic, and gender-based.

For liberation theology, theology is only a second moment—a moment of reflection on the actual praxis of faith—and dominant theologies are, all too often, unconscious sacralizations of the self-interested faith praxis of the elites. Theological work requires, therefore, an effort of critical social analysis of the social conditions and interests shaping its course, so that all theology moves toward bearing the good news of God’s liberation for the poor and oppressed. But, as Gutierrez would put it, what matters is not the fate of theology (not even of liberation theology), but the fate of the poor and oppressed.

Possibly, however, the most significant and enduring impact of liberation theology—including in places as distant as Chile, the Philippines, Korea, South Africa, and Los Angeles—has to do with its emphasis on the obligation of theology and theologians to involve themselves in the actual struggles for liberation of the oppressed themselves. One major facet of this emphasis on praxis are the so-called “basic ecclesial communities” (BECs): small gatherings of lay Christian neighbors—with or without a pastor present—to read the Bible in community, reflect on its practical demands for the larger life in community, and organize and mobilize to enact those demands in the real existence of the area. Such BECs sprouted in many places in South America and beyond (notably in Brazil, with estimates of more than 100,000 BECs in the 1980s touching the lives of several million people), turning the message of liberation theology into the actual development of neighborhood clinics, literacy campaigns, independent schools, labor unions, strikes, mass protests, housing projects, and neighborhood cleanups.

The social and political movements leading to the victories of more socially concerned leaders in Latin America from 1979 on (Nicaragua’s Sandinistas, Haiti’s Lavalas, Brazil’s Workers Party, Venezuela’s Chavez, Chile’s Bachelet, and Bolivia’s Evo Morales), are probably inexplicable without factoring in the influence, large or small, of liberation theology and BECs.

These initiatives have placed liberation theology, on the one hand, in dialogue and cooperation with other movements (Christian or not) fighting for social justice, democracy, equality, and peace, and therefore, on the other hand, also in conflict with both the elites—social, economic, political, military, and, often too, religious—of many nations, as well as with those Christians who view their faith from vantage points outside of the liberation of the poor and oppressed.

Liberation theology has been variously critiqued for being more Marxist than Christian; reducing the Christian faith, evangelization, and salvation to this—a worldly, socioeconomic agenda; promoting hatred of the rich, class warfare, and armed revolution; erasing the spiritual dimensions of the Christian faith; turning the church into a political party; and sacralizing the poor while demonizing the wealthy. Liberation theologians, responding more indirectly than directly to such accusations, have nuanced and deepened their reflections, especially from the 1980s on, while inspiring further critical analyses of the complex social and religious dynamics beneath the charges laid against them.

NORTH AMERICAN LINKAGES

The reach, yield, sway, and publicized persecution of Latin American Roman Catholic liberation theology have often created the impression that it is only, or at least mainly, a Latin American and/or Roman Catholic phenomenon. Liberation theology, however, developed simultaneously in North America, too, and, not much later, in Asia, Africa, and the Middle East.

Black liberation theology was the first North American liberation theology. U.S. Hispanic/Latino theologies followed not long after both Black and Latin American liberation theologies. Feminist, pacifist, Native American, Asian American, and Jewish liberation theologies came immediately thereafter, followed by lesbian and gay liberation theologies. Each one has both advanced the critique of the ways in which their own religious tradition has been an unwitting accomplice of oppression, and contributed to reinterpreting such tradition in further solidarity with the victims of oppression and with their struggles for liberation. In the process, several forums have contributed to the dialogue, reciprocal critique, and cross-pollination between these liberation theologies—the most significant being the EATWOT (Ecumenical Association of Third-World Theologians).

At the onset of the twenty-first century, the multiplicity of liberation theologies, as well as the diversity of situations in which they exist, does not allow for any sweeping diagnosis or prognosis. It can be said, however, that it is not possible any longer to preach Christian theology without facing, sooner or later, knowingly or not, the key question raised by liberation theology: What have we done for the poor and oppressed in our midst? Simultaneously, at least in Latin America, it is hardly possible any longer to administer politics (leftist, centrist, or right-wing; civilian or military; governmental or oppositional; democratic or otherwise), without facing the demands of a significant sum of Christians for respect, justice, and peace for all—beginning with the most vulnerable.
LIBERTARIANISM

From the customs of liberal society and the writings of John Locke (1632–1704), David Hume (1711–1776), Adam Smith (1723–1790), and myriad others, there emerged an ideological sensibility dubious of government activism, leery of collectivist urges, and resistant of nationalism sentiments. It learned to accept commercial society and cosmopolitanism, and even celebrate them. It maintains a presumption of individual liberty. The name of this sensibility has varied in time and place, but in the United States since the 1970s the name has been libertarianism.

The signal feature of libertarianism is the distinction between voluntary and coercive action. Coercion is the aggressive invasion (including the threat of invasion) of one’s property or freedom of consent (or contract). Libertarians maintain a logic of ownership whereby owners have a claim to the control and use of their property, a claim good against the world. The logic is exhibited throughout centuries of liberal society in the normal, legitimate goings-on of private parties. It emerges as intuitive and natural. Adam Smith wrote in The Wealth of Nations (1776) that “the obvious and simple system of natural liberty establishes itself of its own accord” (bk. 4, chap. 9). As for the determination of who owns what, there are universal norms, beginning with ownership in one’s own person, and extending to property acquired within the family and in voluntary interaction with others (such as trade, production, and gift relations). Libertarians admit the holes and gray areas, but argue that the distinctions nonetheless hold much water, and that rival ideologies are also plagued by holes and gray areas, even more so.

Libertarians reject any “social contract” device as a way to bring political relations into “consent.” They reject the idea that, whether by virtue of democracy or simply by maintaining residence within the polity, one voluntarily agrees to the government laws one lives under. Government is recognized as a special kind of organization, and might be said to enjoy a special kind of legitimacy, but it does not get a special dispensation on coercion. In the eyes of the libertarian, everything the government does that would be deemed coercive and criminal if done by any other party in society is still coercive. For example, imagine that a neighbor decided to impose a minimum-wage law on you. Since most government action, including taxation, is of that nature, libertarians see government as a unique kind of organization engaged in wholesale coercion, and coercion is the treading on liberty. This semantic, libertarians say, was central in eighteenth- and nineteenth-century custom and social thought, for example in Adam Smith’s treatment of “natural liberty” and through the American founders, the abolitionists, John Stuart Mill (1806–1873), Herbert Spencer (1820–1903), and William Graham Sumner (1840–1910). (Indeed, libertarians will argue that the vocabulary of modern liberalism is in many respects a systematic undermining of the older vocabulary.)

To just about anyone, coercion has a negative connotation. And, indeed, libertarians generally oppose government action. That disposition holds not only against economic intervention, but extends to coercive egalitarianism (the welfare state), restrictions on personal lifestyle (such as drug prohibition), and extensive government ownership of resources. Libertarians also tend to oppose military action abroad, though some libertarians may favor it when they believe that it bids fair to reduce coercion on the whole (that is, across the globe).

Within libertarian thought, there has been much debate over whether the principle of liberty is absolute (that is, 100 percent), or, as Adam Smith held, simply a presumption (say, 90 percent). Most classical liberals regarded it as a presumption, as have the transitional figures Ludwig von Mises (1881–1973) and Friedrich Hayek (1899–1992), both originally from Austria, and the famous American economist Milton Friedman. In judging where coercive government policy should be accepted or even deemed desirable, the “maxim” libertarians appeal to broad sensibilities about consequences, including moral and cultural consequences, of alternative policy arrangements. They do not attempt to set out any complete or definitive characterization of such sensibilities, any algorithm of desirability, and they declare that it is unreasonable to demand that they do so, especially since the same demand is not made of rival ideologies.

In justifying the presumption of liberty, most libertarians, especially economists, emphasize the practical arguments—liberty works better than government intervention—but others have maintained that liberty has an...
**Libertarianism**

ethical authority established quite separately from any consideration of practical results.

The emergence of libertarianism, as such, comes about from the retreat of classical liberalism (particularly after 1900) and, particularly in the United Kingdom and the United States, the concurrent change of the popular meaning of *liberalism*, such that those who kept up cosmopolitan, laissez-faire, antistatist views no longer had a name.

Mises, Hayek, and Friedman clung to the old term *liberalism*. The term *libertarian* was used occasionally, but was really seized by the critical figure of modern libertarianism, Murray N. Rothbard (1926–1995). Beginning in the 1960s, Rothbard reasserted the old definition of liberty and infused libertarianism with a paradigmatic content holding that institutionalized coercion is always wrong and government action always damaging to social utility. Libertarianism implied anarchism. A prodigious polymath and challenging, charismatic personality, Rothbard erected an integrated doctrine for ethics, politics, and economics.

Anarchist hyphenates (such as *anarcho-capitalism*) were discussed also by other libertarian theoreticians, notably favorably by David Friedman and critically by Robert Nozick (1938–2002). Rothbard, David Friedman, and others built on the notion that private ownership and voluntary exchange are intuitive and focal, and hence lend themselves to a kind of spontaneous adoption by decentralized social institutions. They speculated on how there could be a free market in the enforcement of property rights, like private security companies today. Later research on voluntary reputational practices and institutions, exemplified, for example, by credit reporting agencies, would lend support to the view that, in a world where practically all property is privately owned, government police would not be necessary to resolving disputes and maintaining internal order. As for defense from external aggression, Rothbard tended to argue that no foreign government would have plausible cause or the practical means to conquer an anarcho-libertarian society, while David Friedman admitted uncertainties. The anarcho speculations, as well as Rothbard’s extreme claims for liberty, arguably diverted libertarians from the task of developing a persuasive, relevant ideology, and hindered the penetration of libertarian thinking into mainstream discourse.

Many of the same people in the United States who were fashioning modern libertarianism were also busy fashioning the so-called Austrian school of economics, named for the influence of the Austrians Mises and Hayek (who in 1974 was awarded a Nobel Prize in economics). Austrian economics is solidly pro-laissez-faire, but there has always been a tension between two types of thought. One, exemplified by Mises and Rothbard, champions human reason as an engine of discovery of scientific truth and purports to deduce a priori the superiority of voluntary arrangements. The other, inspired by Smith and exemplified by Hayek, criticizes the pretense of knowledge. It views economic processes as a skein of local practices and peculiarities, with their own dialectics of change and correction, and hence largely unknowable to regulators or even the most assiduous intellectuals. Followers of Mises and Rothbard claim a scientific foundation for laissez-faire economics; followers of Smith and Hayek criticize the scientific claims of interventionist economics. All “Austrian” economists are at least broadly libertarian in their policy views, but many libertarians are mainstream in economic method; Milton Friedman and David Friedman, for example, though admiring of Hayek, would be sharply critical of Austrian economics, particularly the Mises-Rothbard version. In fact, Hayek surely had grave misgivings about that as well, and never favored the fashioning of a separate “Austrian” school of economics.

Another important figure in the resurgence of anti-statist ideas was the novelist and pop-philosopher Ayn Rand (1905–1982). Like Rothbard a messianic personality, though with much less learning and scholarship, Rand too set forth a highly integrated belief system, “objectivism.” However, Rand strongly favored government’s function as the keeper of the peace, and, in sharp contrast to Rothbard, an anticommunist foreign policy. She detested libertarianism, and Rothbard attacked her movement as a cult.

Rothbard’s paradigm was so clear and consistent that even the libertarians who soundly rejected his extreme claims for liberty nonetheless found themselves working out their ideas in relation to principles like those he pronounced. Nowadays, there remain loyal Rothbardians, but most libertarians think more in the fashion of Smith, Hayek, and Friedman. They insist that government intervention, including taxation, is coercive, but they take the anticoercion principle to be, not a natural axiom, but a natural maxim. They see government as having at least one important and necessary function—the undoing of other governmental functions. (In contrast, Rothbard’s vision of libertarian social transformation held that after long years of ideological stirrings, there would come the inevitable internal political crisis, yielding to a widespread awakening and some kind of spontaneous, bottom-up institutional house-cleaning.)

Libertarianism joins the mainstream conversation as a political persuasion anchored in the status quo, not some ideal libertarian society, and yet opposed to the status quo, favoring freer arrangements pretty much across the board. It is perhaps best represented by public-policy institutes, such as the Cato Institute and the Independent
Institute, that develop policy argumentation on an issue-by-issue basis. As for the academic world, the most notable libertarian strongholds are the economics department and law school at George Mason University.

Libertarianism is now a broad tent, rooted in policy issues and consistent on the Locke-Smith-Spencer-Rothbard definition of liberty. Within the tent, only a small portion would defend “anarchism,” but all remain radical in the sense that they insist that government intervention is coercive, and on most issues they entertain and quite likely favor abolishing the government agency or interventions in question.

There has also existed since the 1970s in the United States a Libertarian Party. However, libertarians are usually not much interested in it, chiefly because they feel that within the American system third parties are impossible or even damaging to their own cause.

LIBERTY

The etymological origin of liberty is the Latin word libertas, from liber, which means “free.” In the social sciences, liberty and freedom are often used interchangeably. However, in common parlance, a distinction can be made. Freedom is the more general term referring to a lack of restraint in all its manifestations. Liberty, in contrast, is typically used when discussing the political and legal aspects of the human condition, particularly those involving choice.

Liberty, as a political ideal, has had a profound influence over the course of human events going back to the eighteenth century. It was a central theme for both the American Revolution (1775–1783) and the French Revolution (1789–1799). Liberty was a fundamental motivation for the rise of the modern democratic state, capitalist economies, and the concern for human rights. In contemporary practice, a number of freedoms are commonly protected by the state, including assembly, association, press, religion, speech, thought, and trade. The importance and significance of liberty is widely acknowledged. Still, there are fundamentally different understandings about what it means and why it is valuable.

Benjamin Constant (1767–1830), for example, distinguishes between what he calls “liberty of the ancients” and “liberty of the moderns.” Ancient liberty refers to the direct sharing of political power. It is the “active and constant” participation of citizens in the collective governing of their communities. Consequently, it can only be realized in smaller political units such as the city-state. Ancient liberty involves citizens being able to make truly meaningful contributions to political decisions on a continual basis, thus allowing them to play an intimate role in determining the course of their collective lives. This identification of liberty with ongoing collective political decision-making, however, entails the “complete subjection of the citizen to the authority of the community” (Constant [1820] 1988, p. 311). Still, authentic self-government brought such a “vivid and repeated pleasure” (p. 316) that citizens were willing to make great sacrifices to preserve this form of liberty. The problem is that too little value was attached to the rights of individual citizens.

With the emergence of larger political units like the nation-state, ancient liberty was no longer possible. “Lost in the multitude, the individual can almost never perceive the influence he exercises” (Constant [1820] 1988, p. 316). Liberty, therefore, became associated with individual rights and freedoms. This modern liberty consists in “peaceful enjoyment and private independence” (p. 316) for each citizen. It is made possible by legal guarantees such as the rule of law, freedom of expression, property rights, freedom of association, elected political representation, and the right to petition the government. The purpose of modern liberty is to give citizens the opportunity to choose and enjoy their own “private pleasures.” The danger of this type of liberty is that people will get so absorbed in pursuing their personal happiness and interests that they neglect their political responsibilities, thereby allowing the government to overstep its limits.

Another well-known distinction is Isaiah Berlin’s (1909–1997) understandings of negative and positive conceptions of liberty. On the one hand, negative liberty simply refers to the absence of external constraints and
Liberty

obstacles. It is freedom “from.” Liberty, in this sense, is the ability to act without human or institutional hindrances. It is concerned with the boundaries of individual autonomy. Negative liberty deals with the question, “What is the area within which the subject—a person or group of persons—is or should be left to do or be what he is able to do or be, without interference by other persons?” (Berlin [1958] 1990, p. 121–122). Positive liberty, on the other hand, refers to being able to live an authentic or self-directed life. It is the freedom “to.” This type of liberty is associated with concepts like self-mastery and self-realization. It is interested in the question, “What, or who, is the source of control or interference that can determine someone to do, or be, this rather than that” (p. 122).

Berlin notes that negative and positive liberty might be thought of as two sides of the same coin. The former focuses on the freedom that exists when there are no constraints on the individual, and the latter concentrates on the freedom that comes from personal self-determination. Berlin claims, however, that the theoretical development of these two types of liberty has led to divergent understandings. While the meaning of negative liberty remained the same, positive liberty took on a more psychological orientation. Positive liberty became associated with overcoming internal obstacles that thwarted self-mastery. Berlin contends that this understanding of liberty is dangerous because state coercion can be justified as a benevolent action. By coercing people into living according to their supposed authentic desires, the state is simply advancing positive liberty. Overlooked is the fact that individuals are still being constrained against their will and the state is assuming to know better the true interests of its citizens. Appeals to positive liberty, therefore, divert attention from the disquieting contradiction that the state is forcing its citizens to be free. Berlin sardonically observes that, in this case, “true” freedom is obtained “even while my poor earthly body and foolish mind bitterly reject it, and struggle against those who seek however benevolently to impose it” (Berlin [1958] 1990, p. 134).

Even though positive liberty can be used to justify political tyranny, the association of self-mastery with liberty may nonetheless reflect how humans tend to think about what it means to be free, at least in part. Charles Taylor argues that humans do have higher order, life-orienting aims that can be undermined by impulses and desires. Unhealthy indulgences, for example, may harm an individual’s physical well-being. Irrational fears may prevent people from taking advantage of opportunities that are in their best interests. In these types of situations, “is freedom not at stake when we find ourselves carried away by a less significant goal to override a highly significant one?” (Taylor 1979, p. 185)

Positive liberty is also associated with having requisite resources and opportunities to act. T. H. Green (1836–1882), for example, contends that freedom is commonly recognized as involving the “positive power or capacity” to maximize human potential. Liberty involves not simply the lack of constraint; it also includes the ability to successfully pursue personal goals and ambitions. Green contends that this success depends on people having basic protections and services. Moreover, it is society’s responsibility to provide this assistance. Positive liberty, consequently, requires the provision of educational opportunities, safety regulations for the workplace, and adequate housing. Without health and knowledge, people are not able to develop their faculties and make the most out of themselves.

Liberty, variously understood, has been a central concern for liberalism, the dominant political ideology of the modern age. John Locke (1632–1704), for example, considered individual liberty a natural right along with life, health, and property. The state, therefore, had a responsibility to protect the freedoms of its citizens. Thomas Jefferson (1743–1826) adopted Locke’s theme for the Declaration of Independence, asserting that humans “are endowed by their Creator with certain inalienable rights,” including “life, liberty, and the pursuit of happiness.” This concern for individual freedom was further formalized in the first ten amendments to the Constitution, which provide citizens with rights that limit the power of the state.

John Stuart Mill (1806–1873) was also interested in protecting the liberty of citizens to think and act without interference by the state. He provides a seminal defense of civil liberties in his classic work, On Liberty (1859). His justification, however, was not based on natural or inalienable rights; it was based on utility. Mill claims that maximizing individual liberty creates the greatest utility for society. There are three fundamental types of civil liberties that need to be protected: (1) thought and opinion, (2) tastes and pursuits, and (3) association. The limits of these liberties should be based on what has come to be called the harm principle. “The only purpose for which power can be rightfully exercised over any member of a civilized community, against his will, is to prevent harm to others” (Mill [1859] 1978, p. 9).

Jean-Jacques Rousseau (1712–1778) provided a markedly different approach to protecting individual liberty. Instead of trying to limit the power of the state, he sought to align the individual will with the general will, which is the sovereign will of the people. To accomplish this task, there must be the “total alienation of each associate, together with all his rights, to the entire community” (Rousseau [1762] 1987, p. 24). In so doing, each citizen, “while uniting with all, obeys only himself and remains as free as before” (p. 24). The identification of the
individual will with the general will means the state’s decisions are simply reflections of each citizen’s preferences. Consequently, people are not under the subjection of any other person. If citizens have preferences contrary to the general will, then it merely proves that they were “in error” about the good of the community and their true interests.

Liberal political philosophers may justify liberty in terms of natural rights or utilitarianism. They may advocate negative or positive understandings of liberty. Regardless, all liberal political theories share two basic assumptions: Freedom is a key human value and all individuals are equal in some primary sense. Equality is a necessary complement for liberty. At the same time, however, it can provide a significant challenge. The grant of liberty inevitably undermines equality. The imposition of equality inevitably requires restrictions on liberty. The proper balance of liberty and equality, therefore, is an issue that will always have to be addressed by liberal political theories.

LIFE-CYCLE HYPOTHESIS
The life-cycle hypothesis (LCH) is the theory of private consumption and saving developed by the Italian-born American economist Franco Modigliani (1918–2003) and his collaborators in the 1950s and 1960s. The LCH posits that individuals, trying to maintain a stable level of consumption over time, save in their working years for retirement. Consequently, lifetime resources, rather than current income, are what determine the level of consumption. On an aggregate level, growth in aggregate lifetime resources, often as a result of growth in productivity and a shift in demographics, ultimately determines the saving-income ratio in an economy. The macroeconomic implications of the LCH set it apart from the prevailing Keynesian theory at the time, which assumed that the saving-income ratio was determined by level of income.

Modigliani was awarded the Nobel Prize in Economics in 1985, thanks in part to his construction and development of the life-cycle hypothesis. According to the Royal Swedish Academy of Sciences, the LCH represents “a new paradigm in studies of consumption and saving.”

FROM THE GENERAL THEORY TO LCH
The standard consumption theory prior to LCH was established by John Maynard Keynes (1883–1946) in his groundbreaking General Theory, published in 1936. Keynes observed that aggregate consumption was determined by (current) income and would increase as income increased, but not as much. A theory of saving was not formally developed in Keynes’s General Theory, however, it could be derived from the consumption function that the saving-income ratio was determined by the level of income and would increase as income increased. This implication was later found to contradict empirical evidence. U.S. national income accounts data did not show a rising saving rate over time. Nor did cross-country studies reveal that rich countries necessarily saved more.

In 1954 Modigliani first articulated the life-cycle hypothesis in a paper coauthored with Richard Brumberg (d. 1955). The LCH starts out from the framework that a household makes its consumption and saving decisions at any given time based on the household’s lifetime
resources. In other words, consumers choose their level of consumption in each period to maximize their utility subject to the constraint of their lifetime resources. With the added assumption that consumers prefer a stable pattern of consumption over time, it can be readily shown that households must save in their productive years for consumption after retirement.

The seemingly simple formulation of the LCH differed fundamentally with the accepted theory of the time. In the LCH setting, consumption in any period does not depend on current income but rather on lifetime resources; savings in any period, therefore, depend on the difference between lifetime resources and current income. In contrast to the traditional theory, which predicts that the rich save and the poor dissave, the LCH predicts that the rich and the poor save a similar share of their lifetime resources.

Milton Friedman independently reached the same conclusion at about the same time. In the setting of Friedman’s permanent income hypothesis (PIH), lifetime resources are referred to as permanent income, and the difference between permanent income and current income as transitory income. A change in the level of permanent income affects the level of consumption much more than a change in transitory income. However, thanks to Friedman’s assumption of an infinite life span for individuals, the PIH does not share the most important implication of the LCH presented below—that is, the aggregate saving-income ratio is first and foremost determined by the growth in an economy.

It is important to note that the LCH defines savings, $S$, as the change in aggregate private wealth, $W$, that is, $S = \Delta W$. Therefore, the saving rate, $s$, is simply

$$s = S/Y = (\Delta W/W) \cdot (W/Y) = \rho w$$  \hspace{1cm} (1)

where $\rho$ is the growth rate of the economy and $w$ is the wealth-income ratio.

The two common sources of growth in an economy are population growth and productivity growth. In the case of population growth, the intuition is that as more young laborers enter the workforce, they would save more than what the retirees dissave and drive up the saving rate in the economy. Similarly, in the case of productivity growth, the younger population will have higher levels of consumption in their productive years and will save more as well, such that they can maintain their higher level of consumption after retirement. In aggregate, they will save more than the retirees dissave, and the saving rate will go up.

Some of the implications of the LCH are counterintuitive. As one can see from equation (1), the saving rate in an economy is not affected by per capita income in any way. When the wealth-income ratio is constant, the saving rate depends entirely on the growth rate. If there is zero growth in the economy, the saving rate will be zero. A country with a higher long-run growth rate will save more proportionately than a country with lower growth, irrespective of the per capita income level.

The LCH also predicts that the wealth-income ratio is a decreasing function of growth and is largely determined by the typical length of retirement in the economy.

THE EXTENDED LCH

Although the LCH emphasizes the role of growth in savings determination, alternative saving motives and macroeconomic variables can also be analyzed in its framework. These extensions enhance the explanatory power of the pure LCH model.

Bequest had long been considered to be the primary motive for saving before the LCH. It is now generally considered part of the supporting cast. In the extended LCH setup with bequest, receiving an inheritance increases permanent income, and a bequest to the next generation can be considered a choice for the household in addition to consumption in any period. Bequest raises the wealth-income ratio and hence the saving rate. The net effect on consumption depends on whether households pass on more than they inherit.

Literature on the precautionary motive also dates back to well before the LCH. In the extended LCH formulation with uncertainty in future income, households save more so that they can maintain a smooth consumption pattern in case of an unanticipated drop in income. This effect should be more profound for young and old households because they have fewer assets to tap into for this purpose.

Another area of research is forced savings programs, such as Social Security in the United States and pensions. It is intuitive to see the substitute effect of these programs in that they replace private saving. In reality, however, these programs often have the unintended effect of inducing participants to retire early as benefits decline for people working beyond retirement age. The net result is unclear from a theoretical perspective. Ignoring these programs, however, will bias the savings and income measures downward.

Liquidity constraint prevents households from borrowing to maintain their preferred level of consumption when current income falls below permanent income. In the extended LCH with liquidity constraint, households cannot consume more than their current income, which typically results in higher levels of consumption in later years than in earlier years.

Periods of high inflation often cause consumers to overestimate their real income, which leads to undersaving. In addition, when the return on assets does not fully
adjust to the increase in the price level, inflation will reduce the real value of such nominal assets as bank deposits and bonds, and will consequently lower permanent income.

EMPIRICAL EVIDENCE FROM THE UNITED STATES AND CROSS-COUNTRY STUDIES

The LCH variables are not directly observable, making the hypothesis difficult to test. In addition to equation (1), the most commonly tested LCH equation is the consumption function in the form of

$$C = \alpha YL + rW$$

(2)

where $C$ is consumption, $YL$ is labor income, $W$ is wealth, and $r$ is asset return. Note that, under the LCH, $YL$ is not consistent with current income in the national accounts; consumption does not include the portion of housing and durables purchased in a period but consumed later; and saving is not the residual of current income and current consumption but a comprehensive measure of change in nominal and real assets.

Despite these challenges, the LCH has been successful in explaining the saving behavior in many cross-section and time-series studies. Research in the 1960s, when data regarding private wealth in the United States and national income accounts for many Organization for Economic Cooperation and Development (OECD) countries first became available, accounted for the low saving-income ratio in the United States versus "poorer" countries under the LCH framework. Growth has also been proved to be the driving force behind the high saving-income ratio in Japan in the 1960s to 1970s and in China from the 1980s to 1990s.

Many studies have also documented evidence supporting the various extended versions of the LCH discussed above. Bequest and precautionary motives help explain why the wealth-income ratio does not decline as fast as the pure LCH predicts. Renewed interest in liquidity constraint has found the concept helpful in explaining the lower level of consumption in households' early years.

The LCH lends itself well to studying implications of policies designed to influence private consumption and saving, such as the Social Security program discussed above. Interest rate policy affects permanent income through the asset return variable directly and through its impact on housing and stock prices indirectly. In contrast to bequest, deficit financing increases current generations' permanent income at the cost of future generations.

LIFE EVENT MODEL

LIFE EVENTS, STRESS

Interest in the relationship between life events and stress has sparked thousands of studies over the past several decades. The thrust of this research was that any event that required a person to change aspects of his or her life would have negative consequences for psychological and physical health. According to this perspective, whether the event was positive or negative did not matter. Rather, the most important variable in linking stress and illness was whether the event changed the status quo in one's life and required change. Therefore getting married (presumably a happy event for most) is considered more stressful than getting fired at work or the death of a close friend.

The stress associated with life events can be measured in a variety of ways. The Social Readjustment Rating Scale (SSRS) (Holmes and Rahe 1967) is the most widely used of such measures. It consists of a list of forty-three events in nine categories: personal, family, community, social, religious, economic, occupational, residential, and vocational life. The events are intended to represent significant changes in life that require adaptive or coping behavior. Each event is given a score: for example, death of a spouse is given a 100, marriage a 50, and troubles with boss a 23. Individuals are asked to indicate which of the events listed have occurred over a designated period (from six months...
to two years). The sum of the weights for the checked items is then summed as the life-change score for a given individual.

Although the SRRS has been widely used, it has also been widely criticized. The relationship between life events and illness is thought to be small, and problems such as validity of the weights applied, biases in how people remember personal life events, overlap between life events and illness (e.g., change in sleeping habits) that might be related to illness all point to limitations in measuring a relationship between life events and stress (Smith 1993). Importantly, however, the use of this measure has led to an understanding of the type of life events that seem to have the greatest impact on stress levels; those include events that are unwanted, random, uncontrollable, and close together in time.

More recent perspectives on stress and illness appreciate that stress is a complex process involving different types of appraisals and coping as well as short- and long-term consequences. Perhaps the most applied theory of stress—the transactional model (Lazarus and Folkman 1984)—defines stress as a relationship between the person and the environment that is appraised by the person as taxing or exceeding his or her resources and endangering his or her well-being. According to this view, stress is conceptualized in terms of cognitive appraisal and coping, and stress is considered a continuous process. Furthermore patterns of coping are thought to change from one stage of a stressful encounter to another. For example, in the early stages of coping with the breakup of a relationship, one may seek social support from friends in order to get sympathy, understanding, or another perspective. In time one may find it more effective to cope by reinterpreting the breakup in a positive light, such as how it contributed to personal growth or opened up new and better possibilities.

Research has concluded that an important resource for dealing with stress is social support. People who have strong ties with other people are generally healthier and better able to cope with stressful life events. Other people can help reduce stress in a variety of ways by providing different forms of emotional support (e.g., intimacy and a sense of value), informational support (e.g., advice and guidance), and instrumental support (e.g., physical and material assistance). All these sources of support relate to a range of better health outcomes.

Applications of the stress and coping model to a specific stressor, discrimination, illustrates that exposure to potentially stressful events does not necessarily lead to reduced well-being. A stress and coping approach to understanding the experience of discrimination highlights the importance of examining how stressors are cognitively appraised; the coping strategies targets use to deal with stressful events; and the personal, situational, and structural factors that affect cognitive appraisals and coping processes (Major, Quinton, and McCoy 2002). Members of stigmatized groups confront discriminatory events by engaging in a variety of coping responses that can protect them from or make them more vulnerable to the adverse effects of stress (e.g., James, Hartnett, and Kalsbeek 1983; Krieger and Sidney 1996). The ways one responds to stress in general and discrimination in particular are important in understanding outcomes associated with stress.

LIFESTYLES

Lifestyle is a term found in both popular and scholarly literatures, most often referring to health-related behaviors such as drug use and “unsafe” sex, various forms of deviance, and consumption choices. Two of the earliest uses of lifestyles are in the work of psychologist Alfred Adler and sociologist Max Weber. Unlike Freud, Adler viewed human behavior as oriented toward future goals rather than driven mechanistically by the past. In The Science of Living (1929), he employed the concept of “style of life” to describe the individual’s way of striving toward a goal of perfection within his or her particular social context. In contrast to Adler’s focus on the individual, Weber viewed lifestyles as socially structured, introducing lifestyle to differentiate between class and status. Weber argued that classes are defined by their relation to the production of goods, while status groups are differentiated according to their consumption of goods; the various ways in which groups consume goods cluster into distinctive lifestyles.

The common use of lifestyles in popular culture as well as in studies of health and deviance shares Adler’s focus on the individual to explain behavior, often connecting deviant behaviors such as drug use or unsafe sex to individual life decisions. In the scholarly and policy literatures, variables such as nutrition, housing, risk-taking behavior, health attitudes and beliefs, and preventative health behavior are used as primary indicators of lifestyles. In particular, tobacco use, alcohol consumption, diet, and sexual and intravenous drug practices (e.g., prostitution, needle sharing) are used to predict negative health outcomes. Experts in this field agree that individuals who abstain from smoking and drug use, consume alcohol in moderation, eat a healthy diet, refrain from violence, and practice safer sex have better survival rates than those who do not.

While the use of lifestyles in the health and behavioral sciences centers largely on individual practices, a vibrant social science discourse, in the tradition of Weber, points out that risk factors such as those listed above are only proximate causes of disease. A more sociological approach thus examines these lifestyles in terms of the social factors that put certain groups at greater risk for these behaviors in the first place. For example, in A Plague on Your Houses (1998), Deborah Wallace and Rodrick Wallace argue that living conditions in low-income areas—such as overcrowding and persistent displacement due to urban renewal—result in outbreaks of substance abuse, violence, and contagious disease. Similarly, Carol Cunradi et al. (2000) demonstrate a causal link between neighborhood poverty and intimate partner violence. Other sociologists argue that deviant behavior does not inhere in particular individuals but is learned through social interaction. Contrary to the conventional wisdom of the time, Howard Becker, for example, in Outsiders: Studies in the Sociology of Deviance (1963), finds that marijuana smokers do not naturally adopt deviant behavior because of flawed personalities or psychological problems but instead have to learn from others how to smoke marijuana. Later work in the sociology of deviance led to the concept of subcultures, which are characterized by the social organization of deviance as distinctive lifestyles.

The concept of lifestyles also appears prominently in the “culture of poverty” debate (see Lewis 1966). The culture of poverty thesis, widely disseminated in the Moynihan Report (1965), holds that the qualitatively different values held by the poor result in deviant lifestyles, which in turn lead to continued poverty. This argument has been criticized by sociologists such as Herbert Gans (1972, 1995), Ann Swidler (1986), and Elijah Anderson (1999), among many others, for its lack of attention to structural factors such as unemployment, inequality, and discrimination.

The socially structured nature of lifestyles is also emphasized in the sociology of consumption. In his famous study, The Theory of the Leisure Class (1899), Thorstein Veblen argued that the wealthy translate their money into symbols of prestige through “conspicuous consumption” and leisure. Veblen connects lifestyles to social hierarchy and explains that the lower classes emulate the “scheme of life” of the upper class. For Veblen, lifestyles are always observable, external, and conscious—in other words, conspicuous—that is, primarily enacted as vehicles for status and power.

Along these lines, economists, psychologists, and demographers explain lifestyles as sets of shared preferences. Tracing the development of American consumer culture, Lizabeth Cohen in A Consumer’s Republic (2003) reveals that after World War II, merchants and advertisers moved away from treating consumers as a homogeneous group. Instead, marketers sought to “identify clusters of customers with distinctive ways of life and then set out to sell them idealized lifestyles constructed around commodities” (p. 299).

Target marketing both reflected and indeed created particular consumption patterns, defined not only by material goods but also by cultural frameworks for how to live, particularly through techniques such as “slice of life” advertising.

Another seminal work in the consumption literature is Pierre Bourdieu’s Distinction (1984), which argues that the tensions of late capitalism are played out through consumption as social practice. In contrast to Veblen, Bourdieu emphasizes the habitual, internalized, and largely unconscious cultural practices implicated in lifestyles by explaining that people’s class positions predispose them to certain lifestyles, which they experience as
personal and freely chosen. Thus, Bourdieu creates a map of ostensibly natural and individual lifestyles—centered on taste—and reveals their socially patterned, cultural logic. His use of lifestyles is radically anti-individualist: Even seemingly idiosyncratic qualities such as ways of walking and talking are rooted in socially structured material inequality. Bourdieu's approach thus marks a significant advance over sociologists whose use of lifestyle as a secondary marker of class position draws superficial correlations between lifestyles and other variables such as race, ethnicity, political orientation, education, and urban/suburban/rural residence.

More generally, social theorists of contemporary culture, such as Lears (1983), Campbell (1987), and Bauman (1998), do not see a tight connection between class and consumption, instead linking lifestyles to the growing identity crisis of modernity, thus marking a shift from Bourdieu's structural analysis of the role of lifestyles in class reproduction. For instance, Don Slater contends in Consumer Culture and Modernity (1997), that "in theorizing pluralization and identity crisis, two terms keep appearing: 'expertise' and 'lifestyle.' Both denote features of modern life which manage, assuage, and organize anxieties about modern identity and at the same time can be used to exploit and intensify them" (p. 86). Lifestyles, which center on consumer goods, services, and experiences, thus become a vehicle for the modernist project of realizing the self. This centrality of lifestyles indicates, for some theorists, the instability of modern forms of social membership. Anthony Giddens, for example, argues in Modernity and Self-Identity: Self and Society in the Late Modern Age (1991) that the consumption of goods replaces the genuine development of the self. Since the 1980s, "lifestyle" has become increasingly detached from traditional demographic variables—class, race, or gender, for example—and has come to represent personal, voluntary choices about how to consume.

LIKELIHOOD RATIO TEST

LIKERT, RENSIS

SEE Likert Scale.
LIKERT SCALE

The Likert scale is arguably the most widely used type of attitude scale in the social sciences. The typical Likert scale appears as a collection of statements about an attitude object (person, group, institution, idea, etc.) reflecting favorable or unfavorable attitudes toward the object. Each statement is accompanied by a graded-response rating scale, typically with five response choices, the most commonly used being: “Strongly Agree,” “Agree,” “Undecided,” “Disagree,” and “Strongly Disagree.” The respondent is instructed to select one of the response choices for each statement. To score the scale, the response choices are given weights to reflect the attitude continuum, typically weights of 1 to 5, 1 for the most unfavorable (or least favorable) attitude and 5 for the most favorable. The weights for the respondent’s choices are then summed across all statements. The resulting total score may be interpreted normatively, with reference to some comparison group, or absolutely, with reference to theoretically or empirically chosen cut-off scores.

As examples, here are two contrasting items from a Likert scale on attitudes toward work:

1. Work is an activity to be avoided.
   - Strongly Agree
   - Agree
   - Undecided
   - Disagree
   - Strongly Disagree

2. Work brings out the best of my abilities.
   - Strongly Agree
   - Agree
   - Undecided
   - Disagree
   - Strongly Disagree

The first item reflects an unfavorable attitude toward work and therefore “Strongly Agree” is scored 1, “Agree” is scored 2, and so on, up to 5 for “Strongly Disagree.” The second item, reflecting a favorable attitude, is scored 5 for “Strongly Agree,” 4 for “Agree,” and so on, up to 1 for “Strongly Disagree.”

The format of five response choices per statement is so widely used that some have mistakenly called any instrument using this format a Likert scale. But it is not the five-choice format that characterizes a Likert scale. Rather, it is the method used in developing the scale—Rensis Likert’s method—that makes an instrument a Likert scale, regardless of the number of response choices used.

Likert’s method is essentially the construction of an internally consistent scale. Likert’s idea, innovative for its time in the 1930s, was to use total score as the criterion for item selection, on the assumption that total score was a “best estimate” of a respondent’s attitude. Likert proposed two different methods of item selection: (1) item analysis, in which selection is based on the correlation of item score with total score; and (2) the employment of a criterion of internal consistency, which is used to examine, for each statement, the difference in average item score between high-scoring and low-scoring groups defined on the basis of total score. Both methods turned out to be variants of the same general method for constructing internally consistent scales.

Likert’s insight was that psychometric methods (at that time used only in ability and achievement test construction) could be applied to attitude measurement, just as Louis Thurstone’s insight was that psychophysical methods, such as the method of equal-appearing intervals, could be used in attitude measurement. Louis Guttman, the third pioneering great of attitude measurement, invented a unique scaling method based on a rigorous definition of unidimensionality and its implications for the rank-ordering of attitude statements and respondents. Whereas Thurstone’s method scaled stimuli (attitude statements) and Likert’s method scaled responses and respondents, Guttman’s method scaled both stimuli and respondents simultaneously. However, Guttman’s method was rather difficult to apply, and Thurstone’s method was quite labor-intensive. Consequently, Likert’s method became the method of choice for constructing attitude measures and other self-report instruments, especially with the advent of computers and statistical computer programs. Nowadays, the application of Likert’s method often begins with a factor analysis of a large pool of statements, followed by the (Likert) scaling of high-loading statements for each factor. The usual criterion for item retention is contribution to internal consistency reliability. All the techniques of psychometrics, including—more recently—item response theory, can be applied to the construction of Likert scales.

Likert scales are essentially rating scales, hence they are susceptible to the problems of rating scales. Many of these problems involve response sets, which comprise response tendencies that are independent of the semantic content of the attitude statements. Response sets may result in errors of three kinds: (1) mean error, the tendency to center responses around some preferred mean value (leniency error, when the preferred mean is high, and strictness error, when the preferred mean is low); (2) variance error, the tendency to restrict or to expand the rating range regardless of correspondence to reality; and (3) covariance error, the tendency to rate all statements similarly (also called the halo effect). These errors may be avoided or minimized by various procedures described in psychometric texts.

Likert scales are also self-report scales, hence they are susceptible to the biases implicit in self-disclosure. Clerical errors aside, responses to a Likert scale reflect the extent to which a respondent decides to “self-disclose,” which, in turn, depends on the ability and the motivation of the respondent to self-disclose. Ability to self-disclose is...
affected by such factors as reading comprehension (of the scale's statements, instructions, etc.), experience, and familiarity with the subject matter of the scale. Motivation to self-disclose is more difficult to parse; respondents may be motivated by any number of reasons to understate or to overstate their attitudes. Such distortion may be avoided or minimized if the scale administrator has credibility and rapport with the respondents.

Likert scales can be measures of either stable or changeable attitudes. It behooves scale constructors to determine which kind of attitude they are measuring by conducting test-retest and longitudinal studies. These studies are especially important when the scale constructor intends (for theoretical or other purposes) to measure one kind of attitude rather than the other.

Finally, unless it is actual self-report that is of interest (as, for example, in opinion surveys), Likert scales should be validated against other independent indicators of the attitude(s) being measured. As psychometric instruments, Likert scales have to meet the basic psychometric requirements of reliability and validity.

LIMITS OF GROWTH
The proposition that economic growth could not continue indefinitely was first put in a formal quasi-mathematical manner by Thomas Malthus’s (1766–1834) pamphlet An Essay on the Principle of Population (1798). Malthus’s essential propositions were that “population, when unchecked, increases in a geometrical ratio. Subsistence increases only in an arithmetical ratio. A slight acquaintance with numbers will shew the immensity of the first power in comparison of the second” (Malthus 1798, chap. I.18).

Malthus’s analytic concept, of a clash between variables growing at fundamentally different rates, failed to take root in economic methodology, which instead came to be dominated by concepts of stability and equilibrium. Also, contrary to Malthus’s assumptions, both food and income per capita grew in Europe over the next two centuries.

However, world population also continued to grow, and at an accelerating exponential rate, rising from about one billion in Malthus’s time to four billion by the early 1970s. The specter of population outstripping food production was again raised by the biologist Paul R. Ehrlich in The Population Bomb (1968). The oil engineer M. King Hubbert (1956) hypothesized that economic growth would exhaust oil supplies during the twenty-first century. And, in The Limits to Growth (1972), Donella Meadows and colleagues argued that complex interactions between population, resources, and pollution would limit economic growth.

Ehrlich’s analysis, like Malthus’s, focused predominantly on the relationship between population and food output. On the basis of verbal hypotheses, Ehrlich presented a number of future scenarios with short-term quantitative predictions that were soon falsified. The key weaknesses in Ehrlich’s analysis were the extrapolation of short-term trends, and the expectation that these trends would manifest in near-immediate problems. However, these short-term trends were not maintained. For example, Ehrlich’s book coincided with the “green revolution” in agriculture and extensive birth control programs, which undermined his predictions of imminent widespread famines.

Hubbert’s argument differs from those of Malthus and Ehrlich by considering a nonrenewable resource as the limit, rather than food. Hubbert proposed a logistic depletion of total reserves, so that actual oil output would follow a bell-like curve, peaking in the early twenty-first century when approximately half the planet’s finite stock of oil had been mined. Though the model works well for given deposits, its aggregate outcome is disputed. Critics argue that technological change and price incentives will increase the amount of recoverable reserves indefinitely. Adherents assert that the physical limit will ultimately assert itself, thus limiting economic growth because alternative energy sources to oil have lower net energy gains than oil.

Meadows and colleagues present a sophisticated case for limits to growth using a systems dynamics computer model known as World3. The key features of a systems dynamics model are: (1) the model consists of a set of cou-
pled difference or differential equations (that are represented as flowcharts rather than symbolic equations); (2) the model specifies both positive and negative feedbacks between variables; and (3) time relationships between variables are depicted (there is, for example, a fifteen-year lag between the emission of a chlorofluorocarbon molecule at sea level and its entry into the stratosphere, where it will destroy about 100,000 ozone molecules for about one century before decaying).

Whereas Malthus and Ehrlich presumed the rates of population change remained constant, World3 made this and other rates of change depend on feedbacks from other variables. For example, the fertility rate is affected by negative feedbacks from per capita gross domestic product (GDP), social services, and per capita expenditure on birth control—so that increasing incomes reduce the rate of population growth. Overcrowding and pollution are positively linked to the death rate—so that increasing pollution also reduces the rate of population growth.

World3 allows for technological change that enables increased output per unit of input—an effect that reduces the severity of physical constraints on growth over time. The model is also designed to accept different specifications of ultimate physical constraints, while specifying base-level estimates related to known levels in 1970. Physical constraints included both sources, or fixed nonrenewable resources such as land and oil, and sinks, or the capacity of the ecosystem to absorb pollutants.

As an aggregative numerical model, World3 has to reduce some multifaceted phenomena—such as population, food, pollution, and technology—to index numbers that represent each variable's current level and a set of influences on other variables over time. The model's numerical outcomes are thus not predictions but broad scenarios, where increases in some index numbers—for example, pollution—cause severe dampening effects upon others, such as population or average human welfare. The model also operates at a global level, and thus omits the possibility that some interrelations, and therefore crises, may be localized (for example, land degradation problems are more likely to be severe in Africa and Australia than in Europe and Japan).

In *The Limits to Growth*, World3's index values were calibrated to ensure rough compliance of the model with data from 1900 till 1970. The model was then run forward to the year 2100 under a range of different scenarios—starting from "business as usual"—and then adding a layered range of alternative futures, with changes to population growth norms, accepted levels of pollution, rates of technical change, and desired levels of consumption. Differing levels of physical constraints were also considered.

In contrast to Malthus and Ehrlich, the Meadows group concluded that it was feasible that the world could provide a high-quality life for the entire human population for the indefinite future. However, they also concluded that current growth patterns were likely to overshoot this ideal, leading to some form of severe crisis that would cause world population to fall precipitously in the middle of the twenty-first century.

The Meadows study was a popular success, selling millions of copies, but it was also highly controversial. Critics attacked it on four main grounds, asserting that it:

- Applied unrealistically low-capacity constraints
- Underestimated the market's response to price signals and the adaptability of technology
- Based crucial causal relations on inadequate data
- Used an inappropriate modeling technique

The Meadows group rejects these criticisms on the general ground that they result from applying a mistakenly reductionist approach to their holistic study. For example, they allege that the criticism about capacity constraints being set too low ignores the corollary that, with higher capacity constraints, there is an increased likelihood of pollution levels overwhelming the planet's sinks. In their *30-Year Update*, published in 2004, they argue that to really disprove their conclusions, one or more of the following assumptions has to be disproved (Meadows et al. 2004, pp. 175–176):

- "Growth is considered desirable."
- "There are physical limits to the sources of materials … and there are limits to the sinks that absorb waste products."
- "The growing population and economy receive signals … that are distorted, noisy, delayed…. Responses to those signals are delayed."
- "The system's limits are not only finite, but erodable when they are overstressed … there are strong nonlinearities—thresholds beyond which damage rises quickly and can become irreversible."

They also argue that the systems dynamics approach to modeling is superior to the general equilibrium approach favored by economists. One of the disappointments for the Meadows group has been the lack of adoption of systems dynamics methods by other social sciences—and in particular, by economics.

The 1972 report predicted that environmental issues would dominate early twenty-first century politics. That expectation is confirmed by the widespread political acceptance that global warming is occurring—the underlying cause of which is the emission of far more carbon dioxide than the planet's carbon-absorbing sinks can process, and the degradation of those sinks in a feedback
process. CO₂ levels have risen from 325 parts per million at the time of *The Limits to Growth* report to 380 parts per million in 2006, consistent with the report’s predictions.

Nicholas Stern (2006), using accepted economic computable general equilibrium methods, has amplified the political acceptability of the proposition that global warming will limit growth potential. However, Stern makes much milder predictions of a 5 to 10 percent fall in mid-twenty-first century global GDP because of climate change, and he asserts that addressing global warming will cost only 1 percent of annual GDP. *The Limits to Growth*’s standard run, on the other hand, contemplates a fall in human welfare of more than two-thirds from its peak level. Its sustainable society achieves high human welfare, but requires population stabilization policies, limits on material production, and innovation in food technology, in addition to the power generation, transport efficiency, and pollution abatement contemplated by Stern.

The Meadows group is broadly pessimistic about whether these policies will be implemented in time. In the *30-Year Update*, they argue that humanity’s “ecological footprint” (Meadows et al. 2004, p. xv, following Wackernagel and Rees 1996) exceeded its carrying capacity by more than 20 percent in 2000. They therefore predict that, given the lags in systemic adjustments and the erosion of physical limits, the twenty-first century will experience an “overshoot.” Their policy recommendations, which were intended to avoid overshoot in 1970, are now designed to limit the impact of overshoot to oscillations, and a diminished carrying capacity, rather than a serious collapse.

**LINCOLN, ABRAHAM**

1809–1865

Abraham Lincoln, the sixteenth president of the United States, was born February 12, 1809, in a log cabin in Kentucky. His opinions against slavery seem to have been shaped while he was a boy, partly by his father’s antislavery opinions, partly by the fact that his father took everything Lincoln earned until he was of majority, and partly by a trip to New Orleans where he witnessed the institution in operation.

Lincoln's political career began in 1832, when he ran as a Whig for the Illinois state legislature from the town of New Salem and lost. He won two years later, though, and began studying law. New Salem was not a promising town, and Lincoln moved to Springfield in 1837. There he honed his legal skills, ultimately becoming one of Illinois’s most prominent attorneys and, in the 1850s, a successful corporate lawyer. It was also in Springfield that he met Mary Todd (1818–1882), whom he married in 1842. They had four sons together, only one of whom lived past eighteen.

After four terms in the legislature, Lincoln was elected to Congress in 1846. To the extent that he made a name for himself in Washington, it was by challenging the grounds on which the Mexican War began. Lincoln was not reelected. Discouraged about politics, he focused on his practice instead. The Kansas-Nebraska Act (1854), which allowed Kansas to decide whether it would have slavery and sparked a virtual civil war within the territory, reengaged Lincoln. He won his fifth legislative term but resigned to run for the U.S. Senate, a campaign he lost in 1855.
The following year, he joined the Republican Party, which positioned him for his most dramatic campaign to date; his 1858 race for the Senate against one of the country's best-known Democrats, Stephen A. Douglas (1813–1861). Lincoln's acceptance of the nomination has come to be known as his "House Divided" speech. Equally famous is the series of debates he had with Douglas in seven different towns across the state. The Lincoln-Douglas debates drew thousands of observers and national press attention as the two men argued about whether or under what circumstances slavery should be allowed to spread into the territories. Douglas tried to undermine Lincoln by painting him as an abolitionist (Lincoln actually did not target slavery in the states where it already existed; his goal was to keep it from moving into the territories), and Lincoln pressed on the moral aspect of slavery and Douglas's position. Lincoln lost the contest, but gained nationwide recognition, which he leveraged in a prominent 1859 speech at New York's Cooper Union.

Despite Lincoln's rising prominence, he remained a man with little political baggage. That made him an appealing compromise candidate for the Republicans at their 1860 convention. In November Lincoln ran against three other candidates, including his old nemesis, Douglas. Lincoln won with just 39.8 percent of the popular vote, but a clear majority of electoral votes.

Despite Lincoln's repeated assertions that he was interested only in keeping slavery out of the territories, southerners were convinced that he wanted to abolish it completely and immediately. South Carolina was the first state to secede from the Union, on December 20, 1860. Six states followed shortly thereafter, and four more joined after the rebels opened fire on Fort Sumter on April 12, 1861.

Lincoln initially believed that a number of Unionists in the South would rise up against the Confederate government, so for the first year of the war he favored a strategy that avoided targeting slavery. As late as the spring of 1862, Lincoln believed in trying to compensate slaveowners in places such as the border state of Kentucky for their property, and he thought freed blacks should be sent to colonies elsewhere, on the grounds that blacks and whites could not live together. By July 1862, Lincoln realized that the Confederacy did not have a critical mass of Union supporters, and he decided to hit at the rebels' point of vulnerability. In issuing the Emancipation Proclamation on January 1, 1863 (he had issued a preliminary version the previous September), he believed he was striking at the Confederates in two ways: First, the proclamation would deny southerners their slaves, and second, it would also deny them the workforce that kept the Confederate army going. The proclamation was limited, however, affecting only those parts of the South that were in rebellion and out of the Federals' reach.

Lincoln was fundamentally moderate. He was also a man of his times. Both these points account for his approach to the slavery question as president. Critics have assailed Lincoln's slowness on emancipation, but he believed the Constitution limited his powers in this regard. Because of these constitutional concerns, he issued the proclamation as a military measure. One thing is clear from the historical record, however, and that is that Lincoln was always personally opposed to slavery. He was also willing to change, and he did. In fact, it is difficult to generalize about most of Lincoln's policies because he underwent such transformation in office. For instance, Lincoln abandoned his positions on compensation and colonization and, in the summer of 1864, when he was under great pressure to abandon emancipation as a condition for peace, he staked his career on protecting freedmen, saying he would be "damned" if he abandoned them. He also approved of Sherman's March through Georgia and later into the Carolinas, a maneuver that amounted to hard, if not total, war—a far cry from his gentler approach at the war's outset.

Even as he moved toward harder war, Lincoln wanted a soft peace. His early efforts at reconstruction called for Louisiana to establish a new state government when just 10 percent of the voters in the 1860 election took a loyalty oath and accepted emancipation. Many in Congress deemed this to be too lenient, but Lincoln at the end of his life appeared to be determined to return the rebel states to the fold with as little rancor as possible, while simultaneously protecting and advancing the rights of blacks. This included extending the vote to at least some African Americans. Lincoln was preparing a new reconstruction plan when he was assassinated April 14, 1865—Good Friday—while watching a play. He died the next morning.

While we will never know Lincoln's precise plans for Reconstruction or how they would have changed in response to the contingencies of the day, it seems fair to say that Reconstruction would have been markedly different under Lincoln. Instead, his successor, Andrew Johnson (1808–1875), proved to be a white supremacist who easily bent to the wishes of southern elites. This led to such tragic consequences as the Black Codes, laws that all but reinstated slavery in many parts of the South. Johnson's ready acquiescence to southern demands prompted Congress to wrest control of Reconstruction from the president and impose its own plan on the South, which proved to be to the short-term benefit of black southerners but provoked a bitter and violent response from whites in the region.

LINDBLOM, CHARLES EDWARD 1917–

Raised in Turlock, California, Charles Edward Lindblom attended Stanford University and then went to graduate school at the University of Chicago. Shortly after he began teaching economics at the University of Minnesota in 1939, the department chair rebuked Lindblom “for giving a talk to an undergraduate club on … Lange’s concept of market socialism.” He subsequently “met with many other sharp intolerances” from faculty and did not receive tenure. After moving to Yale, he found greater diversity of thought but nevertheless “was heavily influenced by the intolerances of the discipline of economics” (Democracy and Market System, 1988, p. 17).

Although the tensions were framed in terms of “good economics,” not ideological disagreement, the response to his dissertation (Unions and Capitalism, 1949) was telling: Whereas the text offered a symmetrical analysis depicting corporate and union power relations on a collision course likely to lead to serious problems including inflation, reviewers were sure the author was calling for limits on collective bargaining. Lindblom’s subsequent work reveals that he already was contemplating restraints on corporate executive discretion.

Lindblom’s research questions and methodology were so out of favor that the Yale economics chair urged him to resign, predicting he would “die on the vine” and never be promoted to full professor. However, coteaching and scholarly collaboration with Robert Dahl led to a joint appointment in political science and a gradual shift of attention toward a discipline that recognized the landmark nature of his work. Lindblom chaired the political science department from 1972 to 1974 and later was named to Yale’s most prestigious chair as Sterling Professor of Economics and Political Science. He served as president of the Association for Comparative Economic Studies and of the American Political Science Association.

Lindblom helped found the Institution for Social and Policy Studies, intended to move the university’s social sciences into interdisciplinary conversation while enhancing their relevance to public issues. As director from 1974 to 1980, Lindblom led mapping projects designed to frame research questions with the professional care normally reserved for the conduct of research. Present-day research on the not-for-profit sector traces partly to an exploratory ISPS project, as do Richard Nelson and Sidney Winter’s evolutionary economics and Robert Lane’s studies of market and personality.

In a presidential address to political scientists titled “Another State of Mind” (1982), Lindblom argued that “conventional theory is embarrassingly defective. It greatly needs to call more heavily on radical thought” (p. 20). At four regional political science meetings, he asked audiences: “Suppose—just to limber up our minds—that we faced the fanciful task of designing … a political/economic system that would be highly resistant to change. How to do it?” A “simple and fiendishly clever” approach would be “to design institutions so that any attempt to alter them automatically triggers punishment” (“The Market as Prison,” 1982, p. 324). Far from fanciful, something approaching that arrangement occurs as market systems imprison policy, sometimes via tangible constraints, as when officials fear businesses will move if “excessively” regulated. More insidious and fundamental are imprisonments of mind, a wide range of helpful policy options becoming unthinkable because their adoption would require deviating from tightly held and carelessly examined beliefs about corporation and market.

Politics, Economics, and Welfare (1953, with Robert Dahl) remains the most systematic comparison yet attempted of the price system, hierarchy, polyarchy, and bargaining as political-economic processes of rational calculation and social decision-making. It closes with an insight still fresh generations later: “Through what social processes should action take place? Clearly the answer … (depends on another) question: What kind of human being is wanted?” (p. 523).

The idea of incrementalism introduced therein was refined in “The Science of ‘Muddling Through’ ” (1959), which still garners hundreds of citations annually. The core idea, derived in part from Lindblom’s training in marginalist economic analysis, was a challenge to the Western political tradition’s extreme faith in reason: Analysis is inevitably incomplete, excessively costly, and a poor guide to big changes; political interactions negotiating smaller changes often are both more feasible and more reliable. A Strategy of Decision (1963, with David Braybrooke) and The Intelligence of Democracy (1965)
offered detailed treatments of mutually adjusting interaction as a method of analyzing and determining policy moves, the latter still unparalleled regarding forms of mutual adjustment other than bargaining.

Neither critics nor followers did especially well by disjointed incrementalism. Many readers reduced the concept’s nuances to the oversimplified notion of small steps, degenenrading into arguments that Aaron Wildavsky subsequently pilloried as the search for the “magic size” of an increment. Some perceived incrementalism as overly conservative (Dror 1964, Etzioni 1966), seemingly blaming the decision strategy for conservative tendencies in U.S. politics, or perhaps failing to recognize that, in principle, “a fast-moving sequence of small changes can more speedily accomplish a drastic alteration of the status quo than can an only infrequent major policy change” (“Still Muddling, Not Yet Through,” 1979, p. 520).

Goodin and Waldner (1979) argued that actually practicing incrementalism would be more difficult than it sounds. Some theoretical understanding is needed to decide where and how to intervene, and to determine how long to monitor a policy trial before deciding whether to change it. They pointed as well to difficulties posed by threshold and sleeper effects and questioned the idea that small changes are always less dangerous and more reversible. To the claim that reforms can be thought of as experiments, they found nontrivial difficulties in actually learning from early trials. A number of analysts pointed to circumstances where the value of incrementalism would be reduced, including Schulman’s (1975) recognition that large-scale policy choices such as the lunar program sometimes have to be undertaken completely if they are to work at all.

Lindblom acknowledged the validity of some of these insights but found that the critics had not really proposed an alternative way of grappling with the basic predicament: “Incremental policy making is weak, often inefficacious, inadequate to the problem at hand; and the control over it often falls into the wrong hands. It is also usually the best that can be done,” given the imprisoning effects of corporation and market, gross political inequalities, and elite-catalyzed impairments in political thinking by citizens, government functionaries, and social scientists (Democracy and Market System, 1988, p. 11). Neo-incrementalists recently have begun to take up the challenge, responding to the critics’ concerns and extending incrementalist thought to deal better with inequality and with institutional malfunctioning (Collingridge 1992; Hayes 2001).

Usable Knowledge (1979, with David Cohen) argued that professional social inquiry is “incapacitated in contributing to social problem solving because of its own metaphysics, fashions, traditions, and taboos” (p. 95). Inquiry and Change (1990), another APSA best book award winner, analyzed inequality as a barrier to rationality while contrasting the analysis-heavy ideal of scientifically guided society with a more egalitarian and cognitively realistic self-guiding society. Among many barriers to self-guiding society, foremost is impairment, Lindblom argued: Not only corporation and government, but family, school, church, and media hamper development of capacities for probing problems and possibilities. Social scientists can assist people in understanding and shaping their societies by conducting partisan analysis challenging the status quo better than by aiming for avowedly neutral, supposedly authoritative knowledge that actually is forever unattainable.

Although following in the tradition of the Enlightenment, then, Lindblom’s “aspiration to improve social problem solving ... pursues inquiry and the resourceful utilization of its results more than it pursues firm knowledge. Thus, ... 'Dare to inquire!’” (Inquiry and Change, p. 301).

PRIMARY WORKS
Linear Regression

Social researchers typically assume that two variables are linearly related unless they have strong reasons to believe the relationship is nonlinear. In general, a linear relationship between a dependent variable \( Y \) and an independent variable \( X \) can be expressed by the equation \( Y = a + bX \), where \( a \) is a fixed constant. The value of the dependent variable \( Y \) equals the sum of a constant \((a)\) plus the value of the slope \((b)\) times the value of the independent variable \((X)\). The slope \((b)\) shows the amount of change in \(Y\) variable for every one-unit change in \(X\). The constant \((a)\) is also called the \(Y\)-intercept, which determines the value of \(Y\) when \(X = 0\).

Theoretically, if the dependent variable \( Y \) can be perfectly estimated by the independent variable \( X \), then the \( y \) should be precisely located on the predicted line. The equation of the predicted line can be expressed as \( \hat{Y} = a + bX \). The \( \hat{Y} \) ("Y hat") represents the predicted value \( Y \). However, actual social data never follow a perfect linear relationship. In fact, the actual observed value of \( Y \) is rarely on the predicted line. Therefore, it is necessary to take the deviations between the predicted value and actual value into account through the linear regression model. In the linear regression model, for every \( X \) value in the data, the linear equation will predict a \( Y \) value on the "best-fitting" line. This "best-fitting" line is called a regression line. The linear regression model should then be expressed as \( Y = a + bX + e \). The \( e \) is the error term, or a residual, which represents the distance between predicted value \( (\hat{Y}) \) and the actual \( Y \) value in the data.

The goal of linear regression estimation is to develop a procedure that identifies and defines the straight line that provides the best fit for any specific set of data. A basic approach of linear regression is to estimate, by minimizing the residuals, the values for the two regression coefficients \((a \) and \(b)\) based on the observed data. In other words, the predicted errors estimated by regression equation must be smaller than the errors made with any other linear relationship. To determine how close the predicted scores are to the observed scores, the method of Ordinary Least Squares (OLS) is the most popular approach used in the linear regression.

OLS estimates regression equation coefficients \((a \) and \(b)\) that minimize the error sum of squares. That is, the OLS approach sums the squared differences between each observed score \((Y)\) and its score predicted by the regression equation \( \hat{Y} \), and produces a quantity smaller than that obtained by using any other straight linear equation. The result is a measure of overall squared error between the line and the data: Total squared error = \( \sum(Y - \hat{Y})^2 \).

In Figure 1 the distance between the actual data point \((Y)\) and the predicted point on the line \((\hat{Y})\) is defined as \(Y - \hat{Y}\). The best-fitting line to the data should thus show a sum of absolute values of \(Y - \hat{Y}\) to be the minimum, or the

Linear regression refers to a linear estimation of the relationship between a dependent variable and one or more independent variables.

**SECONDARY WORKS**

sum of distances between $Y - \hat{Y}$ to be the shortest if there are only two sets of $X$ and $Y$. Because some of these distances will be positive and some will be negative, the sum of the residuals, $\Sigma (Y - \hat{Y}) = \Sigma e$, is always zero. The process of squaring removes the negative signs so that the sum of these squared errors is greater than zero. Also, it minimizes the sum of all the squared prediction errors.

Under certain ideal conditions, OLS is in fact superior to other estimators. If these necessary assumptions are true, OLS is the best linear unbiased estimator of corresponding population parameters. The OLS assumptions include:

1. **Linearity.** The relationship between the dependent variable ($Y$) and independent variable(s) ($X$s) has to be linear. But sometimes the true relationship is better described by a curve.
2. **Normality.** It is assumed that $Y$ has a normal distribution for every possible value of $X$. This assumption is especially important in small samples for the marked skewness or severe outliers of residuals.
3. **Homoscedasticity.** It is assumed that the population variance of $Y$ is the same at all levels of $X$. This assumption of homoscedasticity is required for regression $t$ and $F$ tests, as well as difference-of-means tests and analysis of variance.
4. **No autocorrelation.** The sample observations are assumed to be independent of each other if they were individually and randomly selected from a large population. That is, there should be no correlation between errors and $X$ variables (Hamilton 1992, pp. 110–111).

However, perfect data fitted with all OLS assumptions are rather rare in practice. For example, the OLS assumptions may be violated by problems of a nonlinear relationship, omitting relevant independent variables ($X$s) including irrelevant independent variables ($\hat{X}$s), correlation between $X$ and errors, $X$ measured with errors, heteroscedasticity, non-normal distribution, and multicollinearity, and so on. To deal with these problems, certain nonlinear robust estimators are better and more efficient than the OLS estimation, which will yield unbiased estimations of the correlation between $X$ and $Y$ variables. Therefore, the selection of regression techniques is highly dependent on the characteristics of the selected data.

**LINEAR SYSTEMS**

Linear systems are systems of equations in which the variables are never multiplied with each other but only with constants and then summed up. Linear systems are used to describe both static and dynamic relations between variables.

In the case of the description of static relations, systems of linear algebraic equations describe invariants between variables such as:

$$a_{11}x_1 + a_{12}x_2 = c_1$$
$$a_{21}x_1 + a_{22}x_2 = c_2$$

Here, one would be interested in the values of $x_1$ and $x_2$ for which both equations hold. This system of equations can easily be written in matrix form:

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} c_1 \\ c_2 \end{pmatrix}$$

or, more concisely:

$$Ax = c$$

The solution can be written as $x = A^{-1}c$ if the matrix $A$ is invertible. Another frequent application of systems of linear algebraic equations is the following:

$$y_i = b_0 + b_1x_{i1} + b_2x_{i2} + b_3x_{i3} + \ldots + b_mx_{im} + e_i$$

The above is a regression equation stating that for every object $i$, its attribute $Y$ has a value that can be
expressed as the weighted sum of its attributes $X_i$ through $X_m$, with a measurement error of $E$ (whose variance should be a minimum in the classical regression analysis). The term linear is derived from the fact that the graphical representation of the above equation for $m = 1$ is a straight line (with intercept $b_0$ and slope $b_1$). The above equation holds for all $i$, thus the system of equations:

$$y_i = b_0 + b_1 x_{i1} + b_2 x_{i2} + b_3 x_{i3} + \ldots + b_m x_{im} + e_i$$

$$y_2 = b_0 + b_1 x_{21} + b_2 x_{22} + b_3 x_{23} + \ldots + b_m x_{2m} + e_2$$

$$\ldots$$

$$y_n = b_0 + b_1 x_{n1} + b_2 x_{n2} + b_3 x_{n3} + \ldots + b_m x_{nm} + e_n$$

for all $n$ objects is often written in the abbreviated form, using matrices and vectors,

$$y = Xb + e$$

where $y$ and $e$ are column vectors containing all $y_i$ and $e_i$, respectively $(i = 1 \ldots n)$, $b$ is a row vector containing all $b_j$ $(j = 0 \ldots m)$, and $X$ is a $n \times (m + 1)$ matrix (with $n$ rows and $m + 1$ columns) containing $x_i$ in the cells in row $i$ and column $j$ (where $x_{ij} = 1$ for all $i$). Here one is interested in the values of the regression coefficients $b_j$ $(j = 0 \ldots m)$ which minimize the variance of the regression residual $E$. This is solved by calculating $e'e$ which is the sum of the squares of the still unknown $e_j$ and calculating the derivatives of $e'e$ with respect to all (also unknown) $b_j$. These derivatives will be 0 for $e'e = \min, \text{ and the solution of this minimization problem is expressed as follows:}$

$$\frac{\partial b'Xxb}{\partial b} = 0 \text{ for } b = (X'X)^{-1}y$$

Linear systems are also used to describe dynamic relationships between variables. An early standard example from political science is English physicist Lewis Fry Richardson's (1881–1953) model of arms races, which consists of the following simplifying hypotheses:

- • The higher the armament expenses of one military block, the faster the increase of the other block's armament expenses (as the latter wants to adapt to the threat as quickly as it can).
- • The higher the armament expenses of a military block, the slower those expenses will increase (as it becomes more difficult to increase the proportion of military expenses with respect to the gross national product).

Calling the armament expenses of the two blocks $x_1$ and $x_2$, respectively, and their increase rates $x_1'$ and $x_2'$, respectively, one can model the increase rates as proportional both to the military expenses of the other block and the nonmilitary expenses of the own block (the total expenses $x_{1\text{max}}$ and $x_{2\text{max}}$ being constant), with some proportionality constants $a, b, m,$ and $n$:

$$xx_1 = m (x_1^{\text{max}} - x_1) + ax_2 = g - mx_1 + ax_2 \quad g = mx_1^{\text{max}}$$

$$xx_2 = bx_1 + n (x_2^{\text{max}} - x_2) + b + bx_1 - nx_2 = nx_2^{\text{max}}$$

or, in shorter form:

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} g \\ b + nx_2^{\text{max}} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

$$\dot{q} = e + Aq$$

Such linear systems of differential equations usually have a closed solution, that is, there is a vector-valued function $q(t)$ that fulfills this vector-valued differential equation. Usually, the precise form of $q(t)$ is not very interesting, but generally speaking it has the form:

$$q(t) = \theta_1 q_1 e^{\lambda_1 t} + \theta_2 q_2 e^{\lambda_2 t} + q_i$$

where $q_1, q_2,$ and $q_i$ are constant vectors and $\theta_1, \theta_2, \lambda_1, \lambda_2$ are constant numbers of which mainly $q_i, \lambda_1,$ and $\lambda_2$ are of special interest. $q_i$ is the stationary state of the system of differential equations, that is, once the system has acquired this state, it will never leave that state, as the derivatives with respect to time vanish. $\lambda_1$ and $\lambda_2$ are the so-called eigenvalues of the matrix $A$, which, as the exponents of the two exponential functions in the above equation, determine whether the function $q(t)$ will grow beyond all limits over time or whether the two first terms in the right-hand side of the above equation will vanish as time approaches infinity. For negative values of both $\lambda_1$ and $\lambda_2$ the latter will happen, and the overall function will approach its stationary state (in which case the stationary state is called stable or an attractor or sink). If both eigenvalues are positive, then the function will grow beyond all limits (in which case the stationary state is called unstable or a repeller or source). If one of the $\lambda$s is positive while the other is negative, the stationary is also unstable, but is called a saddle point because the function will first approach the stationary state and then move away. There is a special case when $\lambda_1$ and $\lambda_2$ are pure imaginary numbers—which happens if $Aab < 0$ and $m = n = 0$, as $\lambda_{1,2} = -m + n \pm \sqrt{aab + (m-n)^2}$. In the arms race model this is not a reasonable assumption, as one block would increase its arms expenses faster, the smaller the arms expenses of the other block are (exactly one of $a$ and $b$ would be negative and the respective block would behave strangely, the other constant would be positive, so the other block would behave normally) and both would increase or decrease its arms expenses regardless of what their current values are ($m = n = 0$ means that there is no influence of the current value of arms expenses upon its change for both blocks). In this case both variables $x_1$ and $x_2$ oscillate around the stationary state.

The example demonstrates that systems of linear differential equations always have a closed solution, which can be expressed in several different forms. There is always
exactly one stationary state (except in the case that the matrix $A$ is not invertible) that can either be a sink or a source or a saddle or a center. Nonlinear systems often have more than one stationary state, but their behavior can be analyzed in a similar way, taking into account that a linear approximation of a nonlinear system behaves approximately the same in a small neighborhood of each of its stationary states.

**LINGUISTIC TURN**

“Where word breaks off no thing may be”: This line from a poem by Stefan George was repeatedly cited by the German philosopher Martin Heidegger (1889–1976) to indicate his version of the linguistic turn, which affected many philosophers in the early twentieth century—literary scholars already having made the turn, whether consciously or not (Heidegger [1959] 1982, p. 63). The phrase *linguistic turn* actually was coined by the philosopher Gustav Bergman, a former member of the Vienna circle, who made an effort to reformulate philosophy with regard to syntax and interpretation and was given new currency by the American philosopher Richard Rorty (b. 1931). Currently it is extremely popular, but the phenomenon is far from unprecedented (Rorty 1992; and see Jay 1982). Friedrich Nietzsche’s idea of “the infinite interpretability of all things” (Nietzsche [1901] 1967, p. 327) is an analogy drawn from language, and a century later Hans-Georg Gadamer (1900–2002) carried on the criticism of Kant’s transcendental turn (1975, p. 176)—that is, his “metacriticism” of Kant, which Jacques Derrida likewise recalled (Michelfelder and Palmer 1989, p. 102; cf. Derrida 1978). Renaissance humanism, too, was in part a linguistic—a philological, a rhetorical, and a literary—protest against the excessive abstraction of scholasticism, following the lead of the ancient Sophists and orators (Kelley 1991).

The linguistic turn was apparent also in the “new rhetoric” of the mid-twentieth century, which drew attention to the habits and conventions of language, as when Michel Foucault (1926–1984) denied the control of speakers and writers over their own discourse (e.g., Foucault 1970). The arts of speaking and writing are based on conscious imitation, but every literate person moves in linguistic channels carved by predecessors, deposited in the memory, and repeated in different contexts. Particular languages produce semantic fields that make possible communication and dialogue; and linguistic usage—for example, *topoi*, copulas, and word combinations—has its own inertial force that acquires meaning apart from the intentions of users. This is one reason for distrust of the “intentional fallacy” in interpreting texts.

One of the most impressive vistas opened up by the linguistic turn is the modern philosophy of hermeneutics in the form given by Gadamer, who, following Heidegger, extended the line of thought in the direction suggested not by Nietzsche (as did Heidegger and Derrida) but rather by the German philosopher and historian Wilhelm Dilthey (1833–1911). Rejecting revolutionary ruptures as a condition of understanding, Gadamer preserved belief in a kind of continuity that made communication and “dialogue” possible not only between speakers but also over time (Gadamer 1975). There are no absolute beginnings, no understanding without prejudice and the “forestructures of understanding” provided by language and the “life-world.” Pursuing the old quest for “the I in the Thou,” Gadamer accepts the horizon-structure of experience but doubles it to accommodate the contexts of past as well as the inquiring present. Language is a continuum making interpretation possible, but it does not permit the sort of retrospective mind reading assumed by the “empathy” of Romantic hermeneutics. That meaning is always constructed in the present is the hermeneutical condition of Gadamer’s historicism. To understand, in short, is always to understand differently.

An important offshoot of hermeneutics is reception theory, or reception history (*Rezeptionsgeschichte*), which follows Gadamer in shifting attention from writing to reading. In fact, intellectual history is more concerned with the intention of authors and meaning of their texts than with their “fortune” in later contexts. Paul Ricoeur’s “semantic autonomy” of texts is the condition of interpretations and misinterpretations accompanying the reception of writings (Ricoeur 1981, 63ff). For him, the poles of interpretation are hermeneutics of tradition and hermeneutics of suspicion, the first locating the position of Gadamer, who seeks an experience of tradition, the second that of Foucault, who is devoted to the critique of ideology. For Gadamer, “tradition” and continuity produce the common ground of understanding and commu-
communication which, via ideas, connects present and past; for Foucault, they mean entrapment in or complicity with ideology and a denial of the ruptures between the successive epistemes that represent decipherable codes (critically fabricated Weltanschauungen) of culture and patterns of underlying power relations.

This is also to some extent the noble dream of the German approach to intellectual history that is the “history of concepts” (Begriffsgeschichte), an effort to reconstruct an intellectual field through the history of terms and families of terms such as the English study of “keywords” (Williams 1983, and see Richter 1995). Under the influence of J. G. A. Pocock, Quentin Skinner, and others, political thought has turned its attention to questions of terminology and vocabulary rather than abstract systems (Pocock 1971; Tully 1988). Likewise, Begriffsgeschichte is a species of cultural history focusing on semantic change and the historical context of ideas, and it depends on metahistorical considerations to determine the meanings behind the keywords being analyzed. Such enterprises began thirty years ago, before databases such as Proteus and ARTFL made possible a much more extensive searching of semantic fields, but nonetheless they have greatly enriched the practices of intellectual and social history after the linguistic turn.

The linguistic turn has had an impact across the whole range of disciplines, whether through the idea of social construction or through the extension of the interpretive method into the human and even the natural sciences (Bernstein 1980; Nelson, Megill, and McCloskey 1987). The result was to place the observer in the field of observation, that is, the discipline, in the search for meaning. In anthropology this meant not the establishment of general “scientific” knowledge, but rather the hermeneutical “interpretation of cultures,” in Clifford Geertz’s phrase (Geertz 1973); and so it was in the other social and human sciences, which after the linguistic turn took language rather than mathematics as the model of understanding. For some scholars this represented the threat of relativism or the basis for a claim to postmodernism, but in any case it permitted a more critical approach to the social sciences.

The “new cultural history” proclaimed in the 1980s also included a linguistic turn, drawing extensively on post-Marxist literary theory and the idea of history as a text to be read. Some social scientists have resisted this move toward the social construction of knowledge, and a decade later a number of scholars affected to take their disciplines “beyond the cultural turn” (Hunt 1987; Bonnell and Hunt 1999). In any case, there is no turning back.

LIQUIDITY

An asset is considered to be liquid if it can be: (1) easily exchanged; (2) quickly exchanged; and (3) exchanged at little or no cost. For example, currency (coins and paper money) is an extremely liquid asset, whereas consumer durables and housing are very illiquid assets. Other assets, such as money in the bank, stocks, and bonds, fall between these two extremes, depending on the nature of their market. Hence, if someone needed to sell illiquid assets to raise money, say, as a result of a bad income shock, he should expect a loss, because he will not get the full value of his illiquid assets in a distress sale.

Even though the goal of holding assets is to obtain a return, firms and consumers regularly hold currency, which offers no return. The reason for this, first put forth by John Maynard Keynes (1883–1946), is that “bills and call loans are more ‘liquid’ than investments, i.e., more certainly realizable at short notice without loss” (1930, p. 59). According to John R. Hicks (1904–1989), this is the first time the term liquid was used to describe the ability of an asset to be converted to cash without suffering a loss, and sets the foundation for Hicks’s subsequent liquidity preference framework (a theory of nominal interest rate determination) and the IS-LM framework (a theory of determination of aggregate output and the interest rate) (see, for example, Mishkin and Serletis 2007).

These Keynesian models lead to the conclusion that an increase in the money supply (everything else remaining equal) lowers interest rates. This is known as the liquidity effect. However, Milton Friedman (1912–2006), the 1976 Nobel laureate in economics, argued that an increase in the money supply might not leave everything else equal, and that there are other possible effects of an increase in the money supply on interest rates, such as the income effect, the price-level effect, and the expected-inflation effect. In fact, the empirical evidence, mainly based on vector autoregressions (VARs), seems to indicate that money and interest rates are positively rather than negatively related, thereby producing a liquidity puzzle. There have been many attempts to unravel this puzzle (e.g., Eichenbaum 1992; Strongin 1995; Christiano et al. 1996). In general, as more variables are introduced and as the VAR specification is refined, it produces results consistent with traditional Keynesian and monetarist analysis (see, for example, Cochrane 1998). A purely theoretical concept that is also due to Keynes is the idea of a liquidity trap—an extreme case of ultrasensitivity of the demand for money to interest rates. In this case, the money demand curve is completely flat in the liquidity preference framework and the LM curve is horizontal in the IS-LM framework, meaning that increases in the money supply are absorbed without any decline in interest rates. Thus monetary policy is without effect and fiscal policy is the only means of economic control. The empirical evidence, however, indicates that although the demand for money is sensitive to interest rates, a liquidity trap has never existed.

Over the years, several measures of liquidity have been employed. For example, for individual assets, liquidity can be measured by a liquidity premium—the lower the liquidity premium, the more liquid (and the more like money) the asset is. If one wanted to obtain an aggregate measure of liquidity, one would add the assets together, giving higher weights to those assets with lower liquidity premiums. In this regard, the money measures currently in use by central banks around the world (known as monetary aggregates) are simple-sum indices in which all financial assets are assigned a constant and equal (unitary) weight. This index is in , where is one of the components of the monetary aggregate , This summation index implies that all financial assets contribute equally to the money total, and it views all components as dollar-for-dollar perfect substitutes. Such an index, there is no question, represents an index of the stock of nominal financial wealth, but cannot, in general, represent a valid structural economic variable for the liquidity services of financial assets in the economy.

In light of the foregoing arguments, there have been many attempts at properly weighting financial assets within a simple-sum aggregate. With no theory, however, any weighting scheme is questionable. William A. Barnett (1980) applied economic aggregation and index number theory and constructed monetary aggregates based upon W. Erwin Diewert’s (1976) class of superlative quantity indices. The new aggregates are Divisia quantity indices, named after François Divisia (1889–1964), who first proposed the index in 1925. The Divisia index (in discrete time) is defined as

\[
\log M^D_t - \log M^D_{t-1} = \sum_{j=1}^n w^*_j (\log x_{jt} - \log x_{j,t-1}),
\]

according to which the growth rate of the aggregate is a weighted average of the growth rates of the component quantities, with the Divisia weights being defined as the expenditure share averaged over the two periods of the change, where

\[
w^*_j = \frac{1}{2} \left( w_j + w_{j,t-1} \right), \quad \text{for } j = 1, \ldots, n,
\]

is the expenditure share of asset during period , and is the user cost of asset , derived in Barnett (1978),

\[
\pi_j = \frac{R^*_j - r^*_j}{1 + R^*_j},
\]

which is the opportunity cost of holding a dollar’s worth of the th liquid asset.
Above $r_j$ is the market yield on the $j$th asset, and $R_t$ is the yield available on a benchmark asset that is held only to carry wealth between multiperiods. At the margin, the greater the difference between $R_t$ and $r_{jt}$, the greater is the liquidity services that asset $j$ yields.

LIQUIDITY PREMIUM

Liquidity premium is the amount of monetary return that one would be willing to forgo for the convenience or security of disposing of an asset quickly and with minimal or no cost. The power of disposal of an asset is measured in terms of how easily it can be sold as well as in terms of the degree of expected capital risk if the asset is liquidated (Keynes [1936] 1964, p. 226).

Each asset has an expected total return (an “own rate of return”) composed of $q$—the expected income from employing the asset in production; $c$—the carrying cost; $a$—the expected capital gains (appreciation or depreciation); and $l$—liquidity premium. An own rate of return for an asset is calculated in the following way: $q - c + a + l$. Thus liquidity premium is one of the elements that constitute the value of an asset. Assets are differentiated according to combinations of expected monetary returns and liquidity premiums they are anticipated to offer (Carvalho 1999, p. 126).

The state of expectations refers not merely to subjective assessments of what events might or might not occur but also to the anticipated costs of undertaking alternative courses of action (Kregel 1998). So long as there are alternative ways to store value and money is one of them, the option of not “using” money—that is, not purchasing capital assets—and hedging against uncertainty affects investment in less liquid capital assets (Davidson 1978). Thus liquidity premium is an expression of the “return” from holding money as an asset (Keynes [1936] 1964, p. 227). This return establishes the standard that expected yields of capital assets must achieve. In order for capital assets to be purchased, their prices must be at a level at which the expected yield ($q - c$) equals the liquidity premium $l$. Consequently the expected return of a capital asset has to be such as to compensate for its degree of illiquidity given the degree of uncertainty felt by asset holders. The degree of uncertainty determines the liquidity premium (Carvalho 1999, p. 127).

Liquidity reduces the uncertainty about fulfilling future commitments and, implicitly, about future income and capital returns. The willingness to borrow and purchase capital assets depends on business enterprises’ perception of borrower’s risk, whereas the willingness of banks to make the requested loans depends on their perception of lender’s risk (Minsky 1975). The assessment of these types of risks depends on the state of expectations and on the margins of safety or the amount of monetary returns that borrowers and lenders are willing to forgo to be liquid—in other words, on liquidity premium.

These margins of safety vary across time and geopolitical space with the tendency for perception of higher risks and thus with higher liquidity preference in developing countries (Dow 1995, p. 8). At the international level, this can result in a tendency for liquid portfolio investment rather than greenfield foreign direct investment in “emerging markets.” Because liquidity premium is a manifestation of the margin of safety thought necessary to deal with uncertainty and perceived capital risk, it enters the
determination of domestic and global level composition of investment, output, and employment.

LIQUIDITY TRAP
The inability of a nation’s central bank to decrease the interest rate when it is already very close to zero is known as the “liquidity trap.” It was first referred to by John Maynard Keynes in his 1936 “General Theory.” It was John Hicks, however, who—by laying the foundations of the IS-LM model in the 1930s in an attempt to present and popularize Keynes’s main propositions—put forward the concept of the liquidity trap and its policy implications.

The IS-LM presentation of an economy became a very popular tool for macroeconomic analysis and for policy propositions after World War II (1939–1945). In an IS-LM model, the IS curve is a negatively sloped curve that presents the locus of points in which investment (I) equals savings (S) for all possible combinations of interest rates and levels of output (Y). The LM curve is a positively sloped curve that presents the locus of points in which the demand for money or liquidity preference (L) is equal to money supply (M) for all possible combinations of interest rates and level of income (Y). The intersection point of the two curves represents the equilibrium interest rate and output of an economy. The IS curve represents the real sector of the economy and it shifts outward to the right when aggregate demand increases (and inward to the left when demand decreases). The LM curve represents the monetary sector of the economy and it shifts outward to the right with an expansionary money policy (and inward to the left with a contractionary policy). Hence, economic analysis based on IS-LM analysis suggests that an appropriate mix of fiscal and monetary policies can bring the economy to equilibrium with full employment.

It is argued that the lower left segment of the LM curve is very flat, and that for very low (close to zero) interest rates it becomes horizontal. The reason is that at very low interest rates, economic agents prefer to keep cash for liquidity purposes. Financial assets are not as desirable in this situation because their liquidity is lower and their yield is close to zero. Hence, the liquidity preference schedule becomes infinitely elastic due to investors’ expectation that the rate of interest cannot fall any further, and because bond prices are so high that no one expects them to rise still higher. In this flat state, the economy is in “liquidity trap,” meaning that interest rates are so low that people are indifferent between holding money or other assets. The demand for money is therefore infinitely elastic.

The liquidity trap hypothesis has led to a theoretical dispute over the extent to which the demand for money depends on interest rates. Neoclassical and monetarist economists argue that the interest rate is determined in the real sector, and that money, by being neutral, makes monetary policy an ineffective tool. Keynesians, on the other hand, argue that interest rates are defined in the money market, and that money is not neutral. In fact, the liquidity trap hypothesis rests on the neutrality of money, whereas Keynes’s analysis of conditions of less than full employment is predicated on the nonneutrality of money. Another implication of a liquidity-trap situation is that neoclassical analysis becomes inconsistent at such low interest rates, since the system can be in equilibrium at less than full employment. In fact, the liquidity trap argument suggests that the neoclassical case has no equilibrium solution; that is, it does not include a positive interest rate that will equate investment and demand.

According to neoclassical analysis, interest rates are the equilibrators of both capital and goods markets. Interest rates keep investment equal to saving at full employment levels, and as a result the real full equilibrium of the economy is independent of nominal prices. The neoclassical proposition, often associated with the quantity theory of money, states that the interest elasticity of money demand is zero, and that with perfect flexibility of all wages and prices (present and future), full employment
will be maintained. On the other hand, Keynes’s suggestion is that a perfectly competitive economy does not, in fact, tend automatically toward full employment. The inflexibility of wages and prices, the low interest-elasticity of investment demand, and the liquidity trap might all suffice to prevent attainment of full employment equilibrium.

According to Keynesians, if the economy is stuck in a liquidity trap, a shift of the IS curve to the left (lower aggregate demand) does not allow for the intersection of aggregate demand and supply curves, suggesting that wages and prices will fall continuously and there will be no equilibrium. In other words, the problem with the neoclassical analysis is that equilibrium output, either on the supply side or on the demand side, does not respond to the price drop in the liquidity-trap case. In fact, as Keynes argued, it is possible for interest rates to fall so low in the neoclassical model that neither an expansionary monetary policy nor falling prices could ever increase the level of demand-side equilibrium output. Thus, with employment determined in the labor market and demand caught in the liquidity trap, the neoclassical model offers no solution.

The British economist Arthur Pigou attempted to remove this inconsistency in the neoclassical model by suggesting that falling prices would increase consumers’ real wealth, leading to increased spending and reduced saving (the “real balance effect”). The rise in real consumption that occurs with falling prices would shift the IS curve out and raise the level of demand-side equilibrium output. This solution to the inconsistency in the neoclassical model generally implies that, after a long period of falling wages and prices, equilibrium will be reestablished. However, in the 1930s, the U.S. economy seemed to reach a different result: a fairly stable low level of employment with wages and prices dropping to a fixed level. Another solution to inconsistencies arising from the neoclassical analysis in liquidity trap conditions is the rigid-wage hypothesis, which allows for the equilibrium intersection between demand and supply.

Keynes mentioned that he was not aware of there ever having been a liquidity trap. Yet in 1998, Japan’s interest rate was almost zero and output had barely changed, even in the face of expansionary monetary policy by the Bank of Japan, the nation’s central bank. Thus, the Japanese government pursued an expansionary fiscal policy in its effort to increase output. The liquidity trap analysis should therefore clearly be part of the argument, which reveals that Keynesian economics teaches us that the automatic adjustment mechanism of competition cannot be relied upon for purposes of achieving certain policy objectives, such as full employment and price stability.

LITERATURE
The word literature can simply mean a body of published texts, as in, “Are you familiar with the literature on global warming?” In a more restrictive sense, it alludes to creative works of the imagination. Conventionally these are divided into poetry, drama, and fiction. This concept of literature is a relatively recent one, first used in the late eighteenth century.

BEGINNINGS
The English word literature derives from the Latin litteratura, from littera (a letter of the alphabet). Most European languages—Romance, Germanic, and Slavic—have direct Latin cognates of similar meaning. Originally, literature in English signified knowledge of books, book learning, and familiarity with letters, that is, written works. Creative writing was termed poesy or poetry in English, irrespective of its form, from the Greek word for “to create.” The earliest forms of poesy or what we would now call literature were the oral narratives of preliterate cultures—myths and folktales—handed down in written form. These include the oldest known literary text, the Sumerian Epic of Gilgamesh (3000 BCE), ancient Egyptian tales from 2000 BCE, Indian poems in Sanskrit (such as the Hindu epics Ramayana and Mahabharata), and ancient Chinese poetry. Homer’s epics, The Iliad and The Odyssey (eighth century BCE), and the tragedies of Sophocles, Aeschylus, and Euripides (fifth century BCE) stand at the beginnings of the Western canon, or the body of literature generally accepted as worthy of study. Indeed, ideas of literary excellence were already present in the Dionysia festivals in Athens, when Greek playwrights competed for prizes. In a comedy that won first prize in 405 BCE, The Frogs, Aristophanes (c. 450–388 BCE) contrasted two preeminent tragedians—Aeschylus (525–456 BCE) and...
BCE) and Euripides (c. 484–406 BCE)—clearly revealing the Athenians’ general familiarity with their dramas. Through attending epic or dramatic performances, a largely unschooled populace could be exposed to *poesy* or *literature*.

Some of the first Greek libraries were established to gather together accurate copies of the prize-winning dramas. The earliest known library—a collection of Babylonian clay tablets—dates from the twenty-first century BCE. Other ancient examples are the libraries at Nineveh (in modern Iraq), at Egyptian temples, and at the temple at Jerusalem, as well as the Hellenistic libraries of Alexandria and Pergamum, established under royal patronage, and Roman libraries, both private and public. The famous Library of Alexandria, estimated at 500,000 scrolls, was joined to a research center (the Museson or Museum), encouraging the systematic study of philology, that is, language and letters. Literary commentary was already practiced in classical Greece; the best-known examples are those of Plato and Aristotle (fourth century BCE), followed in Roman times with Horace (65–8 BCE), Plutarch (c. 46–120 CE), and Pseudo-Longinus (first century CE), as well as the third-century Neoplatonist Plotinus, whose ideas would resound in the romantic era. The work of these ancient Greco-Roman libraries and commentators established crucial ideas of literary evaluation and the literary canon that would influence Renaissance and later scholarship.

“Poetic” works in verse and prose were produced from antiquity through the Middle Ages and the Renaissance without being considered *literature*. In Europe these included imaginative works in Greek and Latin, as well as later texts in the vernacular languages, such as the Norse, Irish, and Germanic epics (including the Old English poem *Beowulf*), courtly love poems of medieval France, the *Divine Comedy* of Dante Alighieri (1265–1321), the tales of Giovanni Boccaccio (c. 1313–1375), the poetry of Geoffrey Chaucer (c. 1342–1400), and the plays of William Shakespeare (1564–1616). The term *literature* first enters English in the late fourteenth century (according to the authoritative *Oxford English Dictionary*) in the original sense of literacy or acquaintance with books.

**MODERN DEFINITION**

It is not until the late eighteenth century, with such developments as the growth of the modern nation-state; the rise of printing, publishing, and literacy; and the move from aristocratic patronage to commercial support of writing, that *literature* came to signify a body of literary texts. In this general sense, literature includes creative writing (poetry, fiction, drama, and essays), popular narratives, and works produced by philosophers, historians, religious and social thinkers, travelers, and nature writers, as exemplified in standard literary histories or reference volumes like the *Oxford Companion to American Literature*. In the more restricted sense of imaginative literature, the definition alludes to what in French is called *belles lettres* or “fine writing” (a term also sometimes used in English but now tinged with the dismissive meaning of light or artificial dabling). Imaginative literature can be defined by its fictional and autotelic nature, the dominance of the aesthetic function within it, and its special use of language, which René Wellek (1903–1995) and Austin Warren (1899–1986) in *Theory of Literature* characterized as follows: “Poetic language organizes, tightens, the resources of everyday language, and sometimes does even violence to them, in an effort to force us into awareness and attention” ([1949] 1978, p. 24). Complexity and appeal to generations of readers are also viable characteristics.

**AESTHETICS AND NATIONALISM**

The nineteenth century brought about an increasing emphasis on the aesthetic properties of literature and the rise of the field of literary criticism, independent of philosophy or rhetoric. The romantic poets fostered a sense of literature as the field of unique genius and stressed the aesthetic experience of reading. Literature was also increasingly seen as an important element in constructing a unified national consciousness and providing citizens with a sense of their cultural heritage, both through the training of students and through the accumulation of literary works in research libraries and their interpretation by specialists. Famously defining the critic’s object of study as “the best which has been thought and said in the world” in his *Culture and Anarchy* ([1869] 1993, p. 190), Matthew Arnold (1822–1888) played an important role in making literature and literary criticism prominent in Anglo-American culture, vying with philosophy and religion as a way to reflect on the world.

In British and American colleges, the core curriculum was already heavily concentrated on the classics, the study of the languages and literatures of ancient Greece and Rome. English literature was introduced in the 1820s at London and other universities, followed much later in the century by Oxford, Cambridge, and American universities, aided by an influx of women entering college. The national literature was seen as offering a valuable unifying cultural tradition, both in Britain after the shock and disruptions of World War I (1914–1918), and in the United States after the Civil War (1861–1865) and massive waves of immigration in the second half of the nineteenth century. The Victorians produced a staggering array of novels, short stories, and poetry to feed a rapidly growing, increasingly literate and middle-class reading public. The
realistic novel became the dominant literary mode in Western literature, with a growing tendency toward a split between lowbrow or popular fiction—due to a proliferation of new subgenres, such as the romance, the mystery, and science fiction—and highbrow literature, made up of critically approved fiction, poetry, and drama.

Modernist literature of the beginning decades of the twentieth century moved away from the realism and naturalism of the nineteenth century, toward experimentation, disruption of chronology and causality, and increasing complexity, a style more suited to developments in the twentieth century. Here T. S. Eliot (1888–1965) played a crucial role in elevating literature to a high art through his poetry and literary criticism, which helped develop the American formalist New Criticism and The Great Tradition (1948) school of F. R. Leavis (1895–1978) in Britain. This led to the mid-twentieth-century view, aptly summarized by Peter Widdowson, of high literature as “a select(ive) and valuable aesthetic and moral resource to replenish those living in the spiritual desert of a mass civilization” (1999, p. 59).

THE CANON AND BEYOND
What is deemed of literary significance or high literature is to a large extent the purview of the national educational system, where academic critics establish the canon of works considered worthy of reading and study at the school and college level. The canon in its original meaning refers to the authoritative set of orthodox, established texts of the Christian church. The biblical canon excludes a number of texts deemed heretical, such as gnostic writings. Similar exclusionary policies have been seen in literary canonization, leading to postmodernist disruptions of the canon under the pressures of new authors and literary theories, including feminism, queer theory, poststructuralism, deconstruction, and postcolonial studies. From the 1960s onward, the canon, long seemingly the domain of dead white males, was opened up to women, people of color, and other minorities. It was again in flux, with the emergence of these new writings and new genres, such as New Journalism or the nonfiction novel, as well as the self-reflective playfulness of postmodern fiction.

Literature is now increasingly in competition with film, television, and other mass media. Nevertheless, it is sustained by a huge publishing industry, bookselling businesses, the school and university systems, academic and public libraries, and the seemingly infinite resources of the Internet. In his study On Literature, J. Hillis Miller notes the crucial feature of creative writing: “A literary work is not, as many people assume, an imitation in words of some pre-existing reality, but on the contrary, it is the creation or discovery of a new, supplementary world, a metaworld, a hyper-reality. This new world is an irreplaceable addition to the already existing one. A book is a pocket or portable dreamweaver” (2002, p. 18). Although threatened by the visual culture of the twenty-first century, literature still retains its unique quality of being able to generate alternative realities through the use of words as signs without visible referents.

LITIGATION, SOCIAL SCIENCE ROLE IN
Judicial opinions have four elements: (1) jurisdiction (the court’s authority to adjudicate this dispute); (2) findings of fact (what happened); (3) conclusions of law (what laws apply to these facts); and (4) order (what the court directs to be done). Social science is utilized in all four parts. For example, social scientists debate the merits of existing and proposed law, and their writings may be brought to the attention of judges, legislators, and government administrators (Meier et al. 1986, and Dixon and Gill 2002). They are most directly active, as participants, in finding fact, usually as expert witnesses. John L. Solow and Daniel Fletcher describe the role of the antitrust economist as “reaching conclusions about factual issues like the existence of market power or barriers to entry, and drawing causal links between firms’ actions, market outcomes, and claimed damages” (2006, p. 31).

The law categorizes two kinds of fact: legislative and adjudicative. Legislative fact is about generalizations. For example, courts often want to know if a screening device (for school admission, or for employment or termination,
for example) is “valid.” But the effectiveness of a device used to screen plaintiffs cannot be tested on them, because validation requires observations on success or failure of persons who achieved the positions the plaintiffs have been denied. As a Fifth Circuit panel observed, “We fail to understand how passing scores conclusively establish the demographics of the qualified applicant pool if passing scores mean nothing with respect to predicting the quality of future firefighters” (Dean v. City of Shreveport 2006, p. 457). A validity study therefore is always legislative fact. The most famous legislative fact argument in litigation, appearing in an appeals brief by Louis Brandeis, was put together by his social scientist sister-in-law, Josephine Goldmark. Brandeis argued that as women are physically and socially different from men, it is appropriate that they have special protective legislation (Muller v. Oregon 1908). In United States v. Virginia (1996), in contrast, plaintiffs’ experts argued convincingly that academically qualified women who could pass the same physical test as men needed only equal assessment.

To accept legislative fact requires that the court extrapolate from one population to another. When faced with an explicit recognition that such extrapolation is required, some judges have been reluctant to do it, despite precedent acceptance by the Supreme Court of Kenneth Clark's “doll studies,” which showed that both white and black children prefer to play with white dolls. Clark had tested some children at issue in the U.S. Supreme Court's decision in Brown v. Board of Education (1954), which held that race is an unconstitutional basis for school assignment, but the Court referred only to his larger studies of children not connected with this case (Beggs 1995). In contrast, a massive study that contended that harsher sentences (particularly for execution) are handed down more often in black-on-white murder cases (i.e., black murderer of a white victim) than in cases involving any other race combination was rejected because it was legislative fact, where what the Court required was evidence that the particular sentence being challenged was tainted with racial bias (McCleskey v. Kemp, 1987). In another example, the First Circuit Court of Appeals rejected a sociologist’s argument that “relies on evidence from one locality to establish the lingering effects of discrimination in another” (Wessman v. Gittens 1998, p. 804).

Adjudicative fact is particular. Much of what the social scientist expert does is devise ways to measure the concepts that seem relevant to the law. Redistricting, jury representation, antitrust, and equal employment opportunity issues inherently call for such social science fact. To show that juries are unrepresentative of “the community,” for example, one needs a measure of that community, as well as of the jurors. Even if population demographics are stable, individuals may come and go, and not be available for jury duty. The Hispanic population may be younger and more likely to be single and renting—and therefore implicitly more mobile—than the non-Hispanic population. As Hispanics tend to live in identifiable areas, one can describe their mobility directly from address-based data sources. Inferring characteristics of a set of people from data describing their tract or block or zip code is called geocoding.

In another example, invalid implicit screening devices may be used to make employment decisions. An implicit device might be a prejudice held, perhaps unknowingly, by the decision-maker, for example, thinking that fat people are lazy. According to R. Matthew Wise, "social framework evidence is the product of social science research that an expert compiles and uses to construct a frame of reference for specific issues central to the resolution of a case" (2005, p. 548). That is, particular evidence offered by such an expert may be an amalgam, applying legislative fact to case-specific attributes. Whether that type of study will be admitted is always in question.

Three other distinctions loom large in explaining the role of the social scientist as expert witness. First, laws are about events, whereas data are almost always about situations. Changing one's residence is an event, but most data describe the population in an area at one time, and then at another. Hiring and firing are events, but the majority of employment-discrimination analyses have compared situations, such as the racial composition of a firm's employees with the racial composition of a subset of a proximate area's workforce. In another example, one seldom observes the collusion implied in some antitrust charges; that event is inferred from situations, such as where stores are located and the prices of their goods.

The complaining party's expert tries to explain the relationship between the outcome and the alleged events, excluding other, benign events that could have led to the same outcome. The defending party's expert tries to show that it likely was benign events that led to the same outcome, and also argues that plaintiffs' descriptions of the situations are themselves incorrect or misleading. An example in which how one defines a variable determines the statistical result is McReynolds v. Sodexho Marriott Services, Inc. (2004), where the plaintiffs' expert does not measure “promotions” as defendant firm defines them. Courts generally dislike plaintiffs' analyses that have not considered alternative explanations for the events complained about. The defendant may prevail merely by criticizing the plaintiffs’ “proof.” For example, “A statistical analysis which fails to control for equally plausible non-discriminatory factors overstates the comparison group and, under the facts of this case, cannot raise a question of fact for trial regarding discriminatory impact” (Carpenter et al. v. The Boeing Company, 2004, affirmed 2006).
Second, the social scientist’s evidence is subject to legal distinctions, such as the difference between disparate treatment (in which actions are at issue) and disparate impact (in which the action’s effect is at issue). Measuring the “cost” of gasoline at its market price (opportunity cost), evaluating damages to resorts from oil spills by lost consumer surplus, failing to distinguish allowable from nonallowable behavior as causes for an outcome in antitrust litigation, and using the wrong basis for a survey are examples of legal mistakes made in social science evidence. See, for example, Rebel Oil Company, Inc. v. Atlantic Richfield Company (1996), In the Matter of Oil Spill by the Amoco-Cadiz off the Coast of France on March 16, 1978 (1992), Williamson Oil Co. v. Philip Morris (2003), Citizens Financial Group, Inc. v. Citizens National Bank of Evans City (2004), and Autozone v. Tandy Corp. (2001).

Third, although both an eyewitness and a social science witness may present adjudicative fact as they see it, the social scientist provides circumstantial evidence. (Social scientists would call it inferential evidence.) Therefore, social science results must be reported probabilistically. The social scientist cannot be “certain” in the way an eyewitness can.

However, no matter how firmly held, eyewitness testimony is often wrong—it, too, is probabilistic. See United States v. Vépsey (2003), referring to Judge Frank Easterbrook’s discussion of probabilistic evidence in Brannion v. Gransley, 1988: “Much of the evidence we think of as most reliable is just a compendium of statistical inferences.”

Estimates of the fallibility of eyewitness identification (legislative fact) sometimes are allowed into evidence, sometimes not. Thus, although a social scientist cannot testify that “X did not do Y,” he may be called upon to testify that although Z says that X did Y, Z may be mistaken; or that such mistakes happen in such and such circumstances, more or less to such an extent. On the fallibility of eyewitness identification, see Munsterburg (1909), Loftus and Monahan (1980), and Bradfield and Wells (2000). Similarly, “forensic” experts often allude to a certainty in their identification (e.g., by handwriting, fingerprints) that social scientists find offensive. Social science research about the fallibility of forensic evidence is sometimes admitted in rebuttal, sometimes excluded.

Geocoding is a powerful method of examining voting patterns, even though individual ballots remain secret. Social scientists have debated whether gerrymandering had been directed by race (impermissible) or party (permissible) in situations when the outcome of the vote is known and the race of the voters is inferred. J. Morgan Kousser attributes the setting of district boundaries to the majority’s attempt to prevent minority successes (1999). In Thornburg v. Gingles (1986) the Supreme Court found race to be too important a factor to let the redistricting stand; and in Hunt v. Cromartie (2001) it found that race was not important enough to disallow the redistricting. (See Grofman 1998 for social science studies concerning judicial redistricting decisions.)

The federal judicial system had no formal rules of evidence until 1975, prior to which judges usually accepted a witness as an “expert” if he was regarded to be one by others in the same “field” (Frye v. United States 1923). Although the institution of rules of evidence gave judges the authority to determine the expertise of proffered experts, decisions at first were little affected. “Junk science” was sometimes determinative (Huber 1991). In Daubert v. Merrill Dow Pharmaceuticals, Inc. (1993) the Supreme Court held that the Federal Rules of Evidence superseded Frye. Trial judges were instructed to exclude expert testimony they found insufficiently reliable or unhelpful to a fact finder.

The decisions of the “Science Evidence Trilogy”—
Daubert, 1993, Joiner v. General Electric Company (1997), and Kumho Tire Co. v. Carmichael (1999)—now govern the use of scientific and technical testimony. Joëlle Anne Moreno describes the slowness with which Daubert principles have been applied to criminal cases, and the resulting bias against rebuttal experts offered by defendants (2004). John V. Jansonius and Andrew M. Gould (1998) and Mark S. Brodin (2004) discuss the problem of applying the Science Evidence Trilogy to social science. Credentials remain important. Practice has not evolved to focus solely on the proposed testimony. For example, in Gary Price Studios, Inc. v. Randolph Rose Collection, Inc. (2006), a proffered expert’s method for evaluating damages was internally contradictory. The judge took pains to show that the witness was not otherwise qualified, when the rules would have allowed him to dismiss the testimony as clearly incorrect and therefore unhelpful.

Subjects amenable to expert study are fast expanding as imaginative attorneys find new ways to argue for their clients. Courts are increasingly willing to hear evidence from statistical models. For example, adjudicative studies based on samples at one time were not acceptable; see United States v. United Shoe Machinery Corp. (1953), in which Judge Wyzanski drew his own sample, breaking that tradition. “The Court arbitrarily selected from a standard directory of shoe manufacturers, the first 15 names that began with the first letter of the alphabet, the first 15 names that began with the eleventh letter of the alphabet, and all 8 of the names that began with the twenty-first letter of the alphabet, and the first seven of the names that began with the twenty-second letter of the alphabet” (p. 305). Now, over fifty years later, the parties’ experts would do the sampling, presumably more skillfully. Opposing
experts may come from different fields. Some judges complain that they do not have the skills to resolve technical disputes, and sometimes they engage their own experts, as the Rules of Evidence permit.

LITTLE RED BOOK

The “little red book” was a Western nickname for the Quotations from Chairman Mao Tse-tung, a collection of Mao Zedong’s (1893–1976) quotations published in 1964 under the auspices of the People’s Liberation Army (PLA). It is most commonly referred to in China as a “little treasure book.” This pocket-sized quotation book contained more than four hundred select quotations from Mao’s speeches and writings. It was widely circulated in China and around the world during the infamous Cultural Revolution (1966–1976). By the time the Chinese Communist Party finally ordered a halt to the printing of the book in February 1979, at least one billion official copies had already been printed. Some estimates put the total as high as five billion copies worldwide. This impressive number made the little red book one of the most popular publications in the world in the twentieth century.

The little red book was born during a campaign to study Mao’s political thought that was initiated in 1959 by General Lin Biao (1907–1971). Hoping to further his own political ambitions, Lin Biao asked the staff of the People’s Liberation Army Daily to compile a small collection of Mao’s quotations in 1964. Its original compiler was Xian Xiaoguang, an editor who worked for the newspaper. Once the book was approved, it immediately became popular among PLA soldiers, since most of them had little education and found it difficult to read Mao’s original writings. Lin ordered that a free copy be issued to every soldier.

When the Cultural Revolution began in 1966, Mao’s personality cult had reached its peak and demand for the quotation book hit an all-time high. After several revisions, the 88,000-word book was finally made available to the public. It soon became a political bible and a source of spiritual inspiration. Every person in China had at least one copy, and its reading and recital became a daily ritual.
People would carry the little red book everywhere and studied it religiously; they could get into trouble for showing disrespect for the book or for misquoting it. The little red book was carried by millions of Red Guards during the Cultural Revolution, and it became a symbol of China's rebellious and revolutionary youth.

The influence of this publication was tremendous. Mao's formal writing was too difficult for ordinary peasants and workers to read, and this quotation book quickly became a useful literacy reader. It also provided a simplified version of Mao's basic ideas and served as a central tool for the widespread political indoctrination of Communist ideology. The little red book socialized an entire generation of Chinese, and some of its passages remain in use today. Nevertheless, the Chinese Communist Party later denounced the book, and blamed it for its harmful effect on the holistic understanding of Mao's thought.

The downfall of Lin Biao and the end of the Cultural Revolution brought an abrupt end to the worship of Mao and his quotation book. In recent years, the little red book has become a popular collectable item. But as a political reader, it has lost its old status.

LIVERPOOL SLAVE TRADE

In 1740 Thomas Augustine Arne set the words of James Thompson's poem "Rule Britannia" to music. This poem emphasized how Britain was a "Blest Isle" of liberty and that "Britons never will be slaves." Yet at the same time Britain was one of the major suppliers of Africans to the Americas as a slave labor force. In the course of the eighteenth century British ships forcibly transported an estimated 2.5 million individuals from Africa. This accounted for 40 percent of an estimated six million Africans carried by ships of all nations.

LIVERPOOL'S ROLE IN THE TRADE

By the 1740s Liverpool had emerged as Britain's leading slave port, eclipsing London and Bristol, its nearest rivals. Rawley and Behrendt point out in The Transatlantic Slave Trade (2005) that the "adroitness of the Liverpool merchant community" was one of a number of factors accounting for Liverpool's rise to prominence (p. 167). The sailing of the Blessing and the Liverpool Merchant in 1700 marked Liverpool's entry into the trade. Over the next century approximately 5,300 slave ships sailed from Liverpool, accounting for almost one-half of 11,000 British slave ship clearances. By the end of the century Liverpool's dominance was still more pronounced, as three-quarters of all British slaving ventures cleared from Liverpool. Behrendt (1991) points out that approximately 779 slave ship captains were active in Liverpool between 1785 and the abolition of the trade in 1807. Many were migrants from Scotland and the Isle of Man, attracted by career opportunities in the trade.

Liverpool vessels traded for slaves at a wide variety of locations on the West African coast, although the Bight of Biafra developed as a particularly important source of supply from the second quarter of the eighteenth century. John Dawson and William Boats, two of Liverpool's leading slave merchants, controlled a significant share of the market at Bonny in the Bight of Biafra in the late eighteenth century. Captains trading at Bonny had to be skilled in negotiating with African merchants for the supply of slaves. They were often assisted in this trade by surgeons who carefully inspected the men, women, and children brought from the interior by African merchants.

CONTEMPORARY ATTITUDES AND ASSUMPTIONS

Copious business records were generated by British merchants who regarded the shipping of enslaved Africans as "morally indistinguishable from shipping textiles, wheat, or even sugar" (Eltis et al. 1999, p. 1). In contrast, few detailed personal accounts of captains engaged in the British slave trade have survived. Three examples are available for eighteenth-century Liverpool: Hugh Crow, James Irving, and John Newton. The best known is undoubtedly Newton, an evangelical clergyman who composed the hymn "Amazing Grace" in 1772. In his Thoughts upon the African Slave Trade, published in 1788, Newton bitterly regretted his former career as a slave captain. He explained that when he commanded the Duke of Argyle and the African between 1750 and 1752 he had no idea that the trade was wrong. He stated that "I never had a scruple
upon this head at the time. … What I did I did ignorantly; considering it as the line of life which Divine Providence had allotted me” (Martin and Spurrell 1962, pp. 98–99).

His profound guilt and contrition are unlikely to be typical of other men engaged in the trade. Crow probably provides a more typical example of how slave traders reacted to abolitionist debate. Reflecting on his slave trading career in Liverpool between 1790 and 1807, Crow asserted that “it has always been my decided opinion that the traffic in negroes is permitted by that Providence that rules over all, as a necessary evil” (Crow 1830, pp. 132–133).

As the letters and journals of James Irving, a Scottish surgeon and captain, were not intended for publication, they provide a more accurate insight into the cultural assumptions and mind-set of a practitioner in the trade. On his third slaving venture, Irving wrote to his wife from New Calabar (Bight of Biafra) in August 1786 and informed her that trade was slow. He estimated that the process of bartering for slaves would take nine or ten weeks. After completing the Middle Passage from Africa to the West Indies, Irving wrote to his wife in December 1786 and informed her that they were awaiting the sale of their “very disagreeable cargo.” He ended this long conversational letter abruptly, and pointed out that “I think I'll desist [writing] as our black cattle are intolerably noisy and I'm almost melted in the midst of five or six hundred of them” (Schwarz 1995, pp. 112–113). Irving’s description of the 526 Africans confined in the stifling heat of the ship’s hold as “black cattle” sheds light on the brutal inhumanity of the slave trade. Irving failed to recognize the humanity of the Africans and viewed them as inferior and eligible for enslavement.

After five voyages as a surgeon, Irving was promoted to his first command. Three weeks after sailing from Liverpool on May 3, 1789, the Anna was shipwrecked on the Atlantic coast of Morocco. Irving and his crew were captured and enslaved and spent fourteen months in captivity. Redeemed through the efforts of British consular officials, Irving remained completely blind to the irony of his situation and within a month of returning to Liverpool had agreed to command another slave ship. Irving had no compunction about returning to his former occupation of enslaving Africans, and his captivity prompted no reflection on the morality of the trade. Despite his personal experience as a chattel slave, he recognized no similarities with the transatlantic slave trade principally because he did not accept that Africans were fellow humans. Irving died during this second captaincy of the Ellen on December 24, 1791. His correspondence indicates how older attitudes sustaining the trade were deeply entrenched, and that a slave trader who valued his own freedom had no qualms about depriving Africans of their liberty.

Historical controversy continues to center on the extent to which Liverpool’s rapid growth in the eighteenth century was linked primarily to the wealth generated by the slave trade. The complex and enduring legacies of the transatlantic slave trade were explored in an exhibition opened at the Merseyside Maritime Museum in Liverpool in 1994. This gallery, entitled “Transatlantic Slavery: Against Human Dignity,” was groundbreaking as it was the first permanent exhibition of its kind in the world. The new International Slavery Museum opening in Liverpool in August 2007 will considerably extend the scope of the original exhibition.

LOAN PULLING

SEE Loan Pushing.

LOAN PUSHING

One of the international social interactions that occurs between countries is lending by banks of one country (the creditor) to individuals or the government of a different
Loan Pushing

Loan pushing refers to the attempt of a creditor with market power to sell a higher volume of credit at a higher rate of interest to a debtor than the creditor would if it lacked market power. The creditor's market power may stem from a low number of credit suppliers or from the formation of a consortium or syndicate of creditors, such as a consortium of four hundred international banks negotiating with a single country. Loan pulling, in contrast, is the effort of a debtor to gain more credit if it is not faced with loan pushing but rather with credit rationing, which means that the debtor does not get as much credit as it would like at a given interest rate. If the debtor has no market power, it will not get more credit than the rationing creditor wants to give it.

THEORY

A theoretical model for loan pushing is presented in Figure 1. Imagine that a bank consortium uniting all banks and a country is the debtor. The debtor would like to incur debt $L$ for any given interest rate $i$ as indicated by the curve $DD'$. All combinations of interest, $i$, and credit volume, $L$, along the line $DU_0$ are considered to be as good as getting no credit. The monopolist creditor gets the amount of money to be lent, $L$, from the world market at interest cost $rL$. The monopolist obtains interest revenue $iL$ and assumes it will get the money back.

The monopolist now can choose between two types of behavior. It can either be customer friendly, offering a contract on the curve $DD'$, or it can look at its profits and try to maximize them. In the latter case, the monopolist creditor will recognize that curves such as $\pi'$ (or $\pi_j$) represent combinations of interest rates and credit volumes that have equally large profits and therefore are called isoprofit lines. But a curve with higher interest and credit volume represents higher profits. The monopolist knows that the debtor will not accept a contract with interest and credit volume making the debtor worse off than getting no credit; the debtor therefore will reject offers represented by points to the upper right of $DU_0$. The highest profit the creditor can get is therefore a combination such as $(L_m, i_m)$. The monopolist can achieve this by telling the customer “either you take this or you get no credit at all.” This is called a take-it-or-leave-it offer. The debtor accepts because it is slightly better off with the contract than without it.

Of course, this scenario works only if there is no competitor offering a better contract to the debtor and only if the monopolist creditor really is a monopolist. Compared to a situation without monopoly power, where the debtor can get $L$ at interest rate $r$, the interest rate is higher and the credit volume is larger, as stated in the definition of loan pushing above. Therefore, $(L_m, i_m)$ is also called the loan-pushing equilibrium, and $(L, r)$ is called the competitive equilibrium.

Now, eliminate the assumption that the creditor is sure to receive its money back with interest. Instead, the creditor may expect sovereign risk—a political problem caused by governments that wish to protect debtors who refuse to pay (repudiation)—and expect to get only some payment, which increases with the money lent, say $b(L)$. This scenario is illustrated in Figure 2. The creditor would want to make sure that it does not lend more than it can get back. If the creditor can impose a punishment $b(L)$ on the repudiating debtor, the creditor would prefer to limit the credit such that the punishment is as large as the money to be paid, $b(L) = (1 + r)L$, or, $i = b(L)/L - 1$. The profit $(i - r)L_m$ after insertion of this constraint with equality is, $b(L) - (1 + r)L$. Its maximum now is where the $b(L)$ curve in Figure 2 has the maximum distance from the $(1 + r)L$ curve, at $L_c$. If the debtor wants less credit, there is no problem; but if the debtor wants more credit, it will not be offered and the debtor is called to be rationed at $L_c$.

UNDERSTANDING THE 1982 DEBT CRISIS

An essential feature of the debt crisis in the beginning of the 1980s was the sharp rise in the world market interest
rate \( r \). If credit markets were competitive, as at the equilibrium \((r, L_c)\) in Figure 1, the horizontal line would shift up and \( L_c \) would fall. Similarly, if the economy is and remains in a loan-pushing equilibrium, it moves along the reservation-utility line \( DU_0 \) to the upper left, resulting in \((L_m', i_m')\) with higher interest rates \( i_m \) and a lower credit volume, as isoprofit lines can be shown to flatten for a higher world interest rate \( r \) and moving from \( \pi^* \) to \( \pi^{**} \).

If the country is and remains in the credit-rationing regime shown in Figure 2, the line \((1 + r)L\) becomes steeper when \( r \) rises, and therefore the profit maximizing point moves to lower credit volumes. However, whereas the evidence described above indicated that there was loan pushing before the 1982 crisis, the evidence after the crisis was that the balance of trade in goods and services had shifted to positive values and credit was limited to ensure that interest could be paid. Basu (1991) suggested that this would indicate that there was a shift from loan pushing to credit rationing. Ziesemer (1997) showed that this is possible if, in terms of Figure 3: (1) the credit-rationing function, \( i = b(L)/L - 1 \), intersects with the \( DU_0 \)-line; (2) the former is flatter than the latter; (3) the initial equilibrium is the loan-pushing equilibrium \( P \); and (4) the increase in the world market interest rate is large enough to come to a credit-rationing equilibrium \( R \) rather than to an equilibrium between \( P \) and the intersection point \( R \).

**BEYOND THE MODEL**

Why is it profit-maximizing to push rather than to ration? There are several answers to this question. First, banks make the salaries of sales agents dependent on profits, \((i - r)L\). Selling more and at higher interest rates maximizes agents’ salaries (Darity 1986).

Second, third parties, such as a firm selling machines to a debtor country paid by the credit money, \( L \), and being a client of the bank(s), may play a role. For example, the client may be a current bad risk that the bank can get rid of by giving the credit, which is used to increase the revenue when the machines are sold. The bank may now substitute a current risk of the firm by a future risk from the debtor country. Or, more generally, the firm has higher revenue and deposits more money in the bank, thus enhancing expected bank profit. Deshpande (1999) extends the loan-pushing part of Basu’s (1991) model to include a third party and a more general cost function. Deshpande also provides anecdotal evidence and discusses the role of large and small banks in a syndicate.

Third, illegal activity may occur. For example, a bank manager may own shares of the firm, which increase in value if the firm can sell machines to the debtor country. A gain for the manager is exchanged for a risk for the bank. Fourth, economies of scale and scope of the bank may be valued higher than the new risk from the debtor country, especially if the latter is perceived to be low.

LOANS

A loan is a type of debt. In general, a loan refers to anything given on the condition of its return or the repayment of its equivalent. All material things can be lent, but the most common type of loan is the monetary loan. Like all debt instruments, a loan implies the redistribution of financial assets over time between the lender and the borrower.

In a monetary loan, the borrower initially receives an amount of money from the lender, which he pays back, usually in regular installments. This service is generally provided at a cost, referred to as interest on the debt. The provision of loans is one of the principal tasks of financial institutions. A loan also may be acknowledged by a bond, a promissory note, or a mere oral promise to repay.

The concept of loans dates back to the very old ages of the agricultural era, when people had started living in organized societies. However, it developed and became widespread with the use of money. Because of biblical injunctions against usury, the early Christian church forbade the taking of interest. In feudal European society, loans were little needed by the great mass of relatively self-sufficient and noncommercial farmers and serfs, but kings, nobles, and members of the church community borrowed heavily for personal expenditures. The role of the moneylender was undertaken back then by merchants and other townsfolk, especially the Jews, while various devices were found for circumventing the prohibition of usury.

The development of money lending among the Jews as their almost exclusive occupation began in the twelfth century, and it was probably the consequence of the persecutions during the First Crusade; Jews at this time could not own land or vineyards, so money lending was one of the few occupations open to the Jews as a means of livelihood. In addition, the Catholic Church's prohibition against money lending for Christians provided Jews with a unique opportunity to step into this void in establishing themselves as bankers. The laws regarding pawn-broking also became increasingly more detailed. During the Middle Ages, local rulers prohibited Jews from occupying most professions, so they were pushed into marginal occupations that were considered socially inferior, such as money lending.

Historically, attacks on usury have often been connected with anti-Semitism. Moreover, Judaism has been a more lenient religion with respect to lending than other religions. The Torah and later sections of the Hebrew Bible criticize the taking of interest, but interpretations of the biblical prohibition vary. One common interpretation is that Jews are forbidden to charge interest upon loans made to other Jews but allowed to charge interest on transactions with non-Jews. However, the Hebrew Bible itself gives numerous examples where this prohibition was evaded. Moreover, legislation concerning the Jews recognized the rabbinical law. According to the latter, for instance, a Jew who had advanced money on a stolen article was entitled to recover the amount he had loaned for it, including interest, if he could swear that he did not know it had been stolen.

By contrast, many religions prohibit the charge of interest. The most prominent example is that of Islam. Sharia, the Islamic law, does not allow the collection and payment of interest (riba). However, as Maxime Robinson demonstrates in his book Islam and Capitalism (1974), even the Islamic prohibition of usury and other kinds of transactions was no barrier to the continuation and elaboration of pre-Islamic capitalistic practices. The Koranic revelation, therefore, did not bring into being an exemplary moral economic system that was fundamentally different from any other existing economic system. Thus, Islamic prohibitions on usury were circumvented with the establishment of Islamic banks. Islamic banks have the same purpose as conventional banks but are believed to obey the rules of Sharia. Islamic banking is based on the sharing of profit and loss and the prohibition of interest. According to a common practice used to lend money for a purchase, a bank might buy the item itself from the seller and resell it to the buyer at a profit while allowing the buyer to pay for it in installments. To protect themselves against default, Islamic banks retain ownership of the item until the loan is paid.

The United States has an old tradition of lending. Americans have long relied on credit, which, for day-to-
day matters, typically took the form of charge accounts with local retailers. In the early years of the United States, when it was primarily an agrarian society, income for many people rested upon when the crops were harvested and sold. Credit and charge accounts, rather than the more structured repayment of an installment purchase, were more individual in nature, relying heavily on the personal relationship between the consumer and the retailer. Credit cards and other more modern and impersonal means of credit and charge-account purchasing became a fixture in the consumer-retailer relationship in the 1950s. However, even today the traditional, more personal and informal types of charge accounts do exist. Without extending some sort of credit to customers, many businesses in the past simply would not have been able to operate. Today’s modern means, the credit card, has greatly reduced the degree to which individual retailers personally extend credit to consumers. However, credit itself remains as essential to the retail economy as it has ever been.

The history of formal lending in the United States is also deeply related to the rise of homeownership in the lower socioeconomic classes. Formal lending, in terms of institutional lending, has long been the means by which many have been able to buy their own home. Before institutionalized lending that was accessible to those who were not wealthy, people relied on private loans or small, regional networks serving a particular ethnic or professional group. These types of lending situations, however, did not nurture and support homeownership in the same ways, or for as great a percentage of people, as does formal or institutional lending today.

The early types of formal mortgages were extended by insurance companies. The terms of these mortgages, however, were often quite risky for the borrower, with the balance of power distinctly tipped toward the lender in ways that would be deemed unfair and even predatory by today’s standards. Savings and loan associations also evolved, although they remained separate from traditional banks, which could offer checking accounts and other services, until the 1970s, when banking regulations changed. Once those regulations changed, savings and loan associations became almost indistinguishable from the typical bank of today, but their loan practices became the universal standard among many of today’s financial institutions. The practices have been revised continuously through the years by regulations meant to ensure that minorities and women were able to have equal access to fair lending.

Today, banks and finance companies usually extend loans against collateral, such as stocks, personal effects, and mortgages on land and other property. Credit activity is considered to be strongly correlated with consumption, and it is expanding due to the gradually decreasing savings rates of typical households. Financial institutions are the ones responsible for extending loans, and they make a large share of their profits out of this activity. The low penetration of loans to an economy, as is the case in the developing countries of central and southeastern Europe, attracts many foreign direct investments in those countries.

Bank loans and credit are considered to be one way to increase the money supply. Policymakers, such as many central bankers, take into account credit growth developments in their decisions about interest-rate movements. Another aspect of the internationalization of loans is the ability of the participants of economic activity—governments, companies, and households—to borrow from abroad under better terms and conditions.

Apart from those who have access to financial markets, the establishment of organizations such as the International Monetary Fund and the World Bank allow the provision of loans to countries experiencing economic problems. This financial assistance enables countries to encounter economic difficulties, reconstruct, and restore conditions for economic growth. Moreover, Muhammad Yunus of Bangladesh, who was awarded the Nobel Peace Prize for providing, through his Grameen Bank, small loans known as micro-credit to poor people without any collateral showed that loans can be accessible and provide support even to those who have no financial security.

LOBBYING

Lobbying is the process by which an organized interest communicates its concerns and preferences to governmental policy makers in order to influence a policy decision. Lobbyists are the individuals who directly attempt to persuade policy makers to take a particular action. They may be full-time employees of a corporation or an interest group, but are often contract lobbyists hired by an interest group. Additionally, governmental employees act as legislative liaisons for their agencies and at the state level a small percentage of lobbyists are volunteers. Regardless of the extent to which lobbying persuades policy makers, a topic debated by scholars, lobbying serves instrumentally at several stages of policy making. Therefore, understanding the process of lobbying complements knowledge of how policy is made.

HISTORY

The first use of the term "lobby" seems to have been in the mid-seventeenth century when the large anteroom near the English House of Commons floor became known as the lobby. It was a public room in which members of Parliament could be easily approached by individuals seeking favors, called lobby agents. In the early 1800s in the United States those who petitioned government officials in lobbies or common areas were called lobbiers and later lobbyists. This label transferred to their petitioning activity, termed lobbying. Members of Congress did not have private offices until after 1900 so influence seekers commonly buttonholed them in the rotunda of the U.S. Capitol. Similarly, state legislators could be easily waylaid in the halls and anterooms of their capitol buildings as private offices did not appear in some states until the mid-1970s.

FORMS OF LOBBYING AND THEIR ROLES

In the United States, lobbying plays a role in all three branches of government, though legislative lobbying gains the most attention in scholarship and in the media. In Congressional and state legislatures, lobbyists provide drafts of bills to sympathetic members who introduce them, given the need to show policy entrepreneurship and in order to lower the cost of bill preparation by staff. Later, in the committee stage, lobbyists focus mostly on rallying their base rather than persuasion. They typically contact two kinds of legislators: those who are sympathetic ideologically to their client and those who represent a constituency in which their company or group has a strong presence. Similarly, on a floor vote, lobbyists again focus mostly on their base, but if necessary they try to persuade fence-sitting legislators to gain sufficient support for the bill’s passage.

Lobbyists provide technical expertise about the issue and expected effects of the policy as well as political intelligence about the electoral consequences of a member's vote. The most important means of presenting information are testimony at committee hearings and contacting legislators directly, tactics used by 95 percent of Washington lobbyists. Lobbyists can more easily contact legislators if they represent an organized interest whose members constitute a significant portion of the legislator’s constituency. Mobilizing a group’s members to contact a legislator, known as grassroots lobbying, has become an important tool in politics. Lobbyists often control another resource—money—in the form of Political Action Committee (PAC) campaign contributions, which may help secure access to legislators and, some allege, influence floor votes. Political scientists caution that many forces besides money influence a congressperson’s vote, and detecting money’s direct impact on voting has been limited.

Lobbying also extends to the federal executive branch and the U.S. court system. Starting with the presidency, since 1974 the Office of Public Liaison has served as the White House’s primary means of interaction with organized interests. Interests gain access to prominent officials, and the White House receives information and lobbying support from organized interests. It is not always clear what the interests gain from this approach. More transparently, interests lobby bureaucrats in the regulatory process. Whenever Congress enacts legislation, an agency must write rules for implementation, a process open to public comments and hearings, in which lobbyists regularly participate. Agencies pay attention to comments because regulations can be legally challenged for a variety of reasons.

Indeed, legal challenges and influencing the courts are also part of the domain of lobbying; however, lobbyists cannot directly contact judges about rulings, so in this approach organized interests use indirect lobbying techniques. The first technique is lobbying during judicial selection. At the federal level lobbyists simply encourage senators to vote for the confirmation of judicial nominees favorable to their group’s concerns, while in the thirty-eight states where judges stand for election, interest groups get more directly involved in campaigning. A second means is actual litigation either through an organization’s defending itself or sponsoring a test case. A final means of influencing courts is by submitting *amicus curiae* briefs on cases with which the organized interest is not involved as a litigant, yet has a policy interest. These briefs advance legal and social arguments that may not be raised by the litigants. When seemingly technical rule-making by bureaucrats or rulings by courts affect policies of interest to their clients, lobbyists attempt to influence these decisions.
REGULATION
In regulating lobbying by organized interests, the primary focus at both the federal and state levels has been on registration and public visibility, rather than restricting activity. Lobbying is protected by the First Amendment, which guarantees the right "to petition the Government for a redress of grievances." The Federal Regulation of Lobbying Act of 1946 was the first law to require lobbyists at the national level to register, but court rulings substantially narrowed the range of groups that had to register. The Lobby Disclosure Act of 1995 established a meaningful registration requirement for nearly all organizations engaged in direct lobbying. In 2005 36,689 individuals lobbied Congress, according to PoliticalMoneyLine, an independent campaign finance Web site. States began oversight of lobbying in the 1960s, primarily by requiring lobbyist registration and disclosure of expenditures. In the 1990s many states tightened their rules, often imposing gift bans, so that in the early 2000s state laws are substantially more stringent than federal law. The Center for Public Integrity reported that 47,000 organized interests were registered to lobby in state capitals in 2004, employing more than 38,000 individual lobbyists.

LOBOTOMY
Lobotomy describes a class of psychosurgical techniques that involve the cutting of nerve fibers in the prefrontal area of the brain with the intent to calm severely disturbed psychiatric patients. These procedures are designed to disrupt the limbic system, the area of the brain most closely associated with regulating emotion.

António Egas Moniz (1874–1955), a Portuguese neurologist, is credited as initiating the widespread use of psychosurgery. In 1935 Moniz attended a presentation by psychologist Carlyle Jacobsen at the Second International Neurological conference in London. Jacobsen noted that destruction of the prefrontal area in monkeys eliminated “experimental neurosis,” a pattern of frustrated behavior in response to errors when monkeys were given problem-solving tasks. Moniz questioned Jacobsen as to whether similar procedures could be used in humans to eliminate anxiety. Moniz and his colleague Almeida Lima initially treated psychiatric patients by using alcohol injections to destroy parts of the frontal lobes. By the end of 1935 Moniz and Lima were performing prefrontal leucotomy, a technique that involved cutting open the skull and severing nerve connections using a surgical instrument with a wire loop on the end called a leucotome.

In 1936 Moniz published encouraging results from twenty patients. Of these Moniz reported fourteen were either cured or showed improvement. Interest in lobotomy and for other dramatic procedures like insulin-induced coma and electroconvulsive therapy grew rapidly in response to the social pressures of a growing number of psychiatric patients in state hospitals during the 1930s and 1940s. Available treatments prior to the rise of psychosurgical techniques consisted primarily of the use of heavy sedatives, such as opiates or barbiturates. Psychoanalysis was growing in popularity but was impractical for widespread use in hospital settings especially among patients with severe disorders, such as those with schizophrenia. In recognition of his contribution to medicine, Moniz was awarded the Nobel Prize in 1949.

Lobotomy’s greatest promoter was Walter Freeman, a U.S. neuropsychiatrist. Freeman corresponded with Moniz and closely followed the reports of his work. Freeman and neurologist James Watts established a practice and began performing their first lobotomies in 1936. Although Watts was trained as a surgeon while Freeman was not, the two often performed the operation together. After performing several surgeries using Moniz’s technique, Freeman and Watts developed a technique that involved drilling burr holes in both sides of the skull to be used as landmarks for making more precise cuts. Their procedure became known as the standard Freeman-Watts lobotomy. Freeman and Watts published Psychosurgery in 1942, which included reports about their patients, descriptions of the procedure, and theoretical explanations.

Freeman became discontent with inconsistent results of standard prefrontal lobotomy—particularly among schizophrenic patients who he felt were less benefited the longer their disorder progressed without psychosurgery. In 1946 Freeman performed the first transorbital lobotomy. Nonsurgical professionals could perform this procedure within a few minutes without anesthesia often during an office visit. The transorbital lobotomy involved inserting a sharp instrument resembling an ice pick through connective tissue between the eye and the orbital bones, and then thrusting the instrument upward to sever neural connec-
tions. After years together Watts split with Freeman over Freeman's characterization of transorbital lobotomy as a minor operation and eager use of the procedure. Freeman went on to perform or supervise approximately 3,500 transorbital lobotomies and train many others to perform them in a tour of state hospitals to popularize the procedure.

The use of lobotomy declined rapidly with the advent of drug treatments in the mid-1950s such as chlorpromazine to treat schizophrenia. Introduction of viable alternatives strengthened support for lobotomy's critics. Critics included Nolan Lewis, director of New York State Psychiatric Institute, who spoke at a psychiatric symposium in 1949 that included Freeman and Watts and challenged the validity of evidence in favor of lobotomy. Lewis claimed widespread underreporting of unsuccessful surgeries. He also questioned whether quieting the patient was really a cure or more a convenience to psychiatric caregivers. Patients were often described after surgery as emotionless zombies, impulsive, or lacking initiative. In a published critique in 1949, Jay Hoffman, chief of the Veteran's Administration's Neuropsychiatric Service, noted that results were typically deemed successful as long as patients showed improvement over their condition during hospitalization, but that family members were often unhappy with the results, as patients did not return to their prediagnosis, normal selves (Hoffman 1949).

Although technical improvements in psychosurgery allow more precise destruction of specific cells or neural circuits, ethical questions surrounding the irreversibility of these procedures have led to legal restrictions limiting psychosurgery to a treatment of last resort.

LOCKE, JOHN
1632–1704

John Locke was an English philosopher who is often seen as the founder of liberalism and a major source of inspiration for the American founding. Born into a Parliamentary family near Bristol, Locke attended the prestigious Westminster school in London and then Christ Church College at Oxford. In 1666 he became a friend and secretary of Anthony Ashley Cooper (1621–1683), later the first earl of Shaftesbury, a prominent Whig politician. After the arrest of Shaftesbury and a number of other Whigs for their opposition to royalism and Catholicism, Locke fled to Holland in 1683, returning to England only after the Glorious Revolution of 1688 expelled James II (1633–1701) and installed William of Orange (1650–1702) on the throne. While he had been working on what were to become his major writings for several decades, it was not until this time that they were published: A Letter Concerning Toleration, which advocated religious toleration and a separation of church and state, the Two Treatises of Government, which argued for limited government and private property, and An Essay Concerning Human Understanding, which advanced an empiricist view of human knowledge, were all published in 1689. While the former two works appeared anonymously, the latter was published under Locke’s name and quickly made him famous. Other important works of his later life included Some Thoughts Concerning Education (1693) and The Reasonableness of Christianity (1695). By the time he died in 1704, Locke had become one of the most prominent and influential philosophers of his time.

The second of Locke’s Two Treatises of Government is often regarded as the founding text of liberalism. In this work, he posits that there is no natural or divine source of legitimate political power and thus that government must be based on consent. In the “state of nature” that exists when there is no political authority, he claims, the law of nature (which obliges people not to harm others) tends to be inadequately obeyed and enforced, and so people agree to create a government through a social contract. The purpose of the contract and hence of government is to protect people’s lives, liberties, and property, and to achieve this end Locke advocates a limited government with institutional safeguards such as separate legislative and executive branches, common judges, and standing laws that apply equally to everyone. Locke puts a special emphasis on the protection of property rights, as he claims this will encourage people to be industrious and thus to increase productivity and raise the society’s standard of living. While people are understood to have tacitly consented to the government under which they live even if they were not a part of the original social contract, the people always remain supreme, and thus when the government violates
its trust the people can and should exercise their right to revolution. With his arguments for natural rights, government by consent, constitutionalism, private property, and religious toleration, Locke is one of the major sources of the ideology of the American founding and indeed of the modern world.

**LOCUS OF CONTROL**

Locus of control was the brainchild of psychologist Julian Rotter, who based his concept on the social learning theory idea that the generalized expectancies of people govern their actions. Rotter assumed that people vary in the degree to which they perceive the things that are happening to them as being under their own internal control or under the control of outside forces. Using this latter locus of control dimension, at one end of the continuum are the internal individuals who see themselves as being “captains of their own ships,” whereas at the other end of the continuum are the external persons who see themselves as being ruled by powerful people or outside forces. In more technical psychological terms, the internal loci of control people believe that through their own behaviors, they have command over the reinforcements in their lives; conversely the external loci of control people see the reinforcements in their lives as being driven by causal sources that are independent of their own actions.

**HISTORY OF CONCEPT**

Since the publication of the 1962 article “Internal Versus External Control of Reinforcement: A Major Variable in Behavior Therapy” by Julian Rotter, Melvin Seeman, and Shephard Liverant, there have been more published papers on this construct than perhaps any other new idea in all of psychology. At the start of the twenty-first century there were literally thousands of studies that focused on locus of control. This surge of interest regarding locus of control probably stemmed from the fact that it represented a logical step as the field of psychology moved beyond the previous strict tenets of stimulus-response behaviorism. On this point Rotter believed that to understand the actions of higher order organisms such as human beings, people’s expectancies about their behaviors being reinforced needed to be taken into account. Thus he reasoned that people use their personal experiences to develop expectations as to whether they can or will be rewarded for their actions. Beyond the inherent appeal of these underlying social learning and generalized expectancies ideas, another reason for the explosion of interest probably was the fact that Rotter produced a short and valid self-report instrument for measuring locus of control. That is to say part of this tremendous growth reflected the availability of a valid instrument for use by researchers.

**RESEARCH EVIDENCE**

In 1966 Rotter published what has come to be called the Rotter IE Control Scale. It contained twenty-three items (plus six fillers), each with a paired option. For each item the respondent is asked to select which of two options is most true of him or her. Thus consider item #2 on the Rotter IE Control Scale, where the respondent is asked to select from the following two choices: option A, “Many of the unhappy things in people’s lives are partly due to bad luck,” or option B, “People’s misfortunes result from the mistakes that they make.” In this item #2 option A represents a response indicating an external locus of control, whereas option B represents an internal locus of control. The more of the external items that the person selects as being most applicable to him or her, the more external is that person’s overall score.

The IE scale has been shown to be reliable and valid. Likewise factor analyses have revealed that the items fall into two clusters, with one factor pertaining to a sense of mastery and a second factor tapping the degree to which citizens perceive that they can play significant roles in political institutions.

Along with Rotter’s IE scale, the following other adult indices related to locus of control have been introduced and validated: (1) the Nowicki-Duke Locus of Control Scale; (2) the Crandall, Katkovsky, and Crandall Intellectual Achievement Responsibility Questionnaire; and (3) the Wallston and Wallston Health Locus of Control Scale. Additionally indices such as the Nowicki-Strickland Locus of Control Scale for Children have been developed for use with children of various ages.

From the outset Rotter suggested that an external locus of control was implicated in neurotic maladjust-
ment. In support of this general proposition persons with external as compared to internal loci of control have been shown to be more unhappy, depressed, and suicidal. Likewise those clients who do not improve over the temporal course of psychotherapy have loci of control scores that remain external, whereas those psychotherapy clients who improve over treatment have scores that have become more internal. Turning to achievement-related performances in school, external loci of control people repeatedly have done more poorly than internal loci learners. Furthermore studies consistently have shown that external more than internal loci of control people have disadvantages in physical health-related matters. Specifically compared to internals, the external loci of control persons have worse sleeping, exercise, and eating patterns, and they also are more prone to hypertension.

The counterproductive outcomes produced by external as compared to internal loci of control persons may relate to many externals’ lack of belief in hard work, along with their unwillingness to expend high efforts. Also because externals believe that their lives are ruled by chance factors and/or powerful forces residing outside of themselves, they are quite passive and do not take protective measures when it comes to health matters (e.g., wearing seatbelts or sunscreen). They also tend not to be planful and future oriented because they do not see themselves as being capable of effective proactive behaviors. As such instead of taking a task-oriented “I can do something” approach to anticipate any stressors that they may encounter, external loci of control people are rather fatalistic about their coping skills in particular and their lives more generally. Moreover the externals relative to internals are not attentive to their surrounding environments, and they are not very knowledgeable about health-related matters. Accordingly the externals probably could not act in healthy ways even if they wanted to do so. Not surprisingly, therefore, externals greatly prefer avoidance behaviors rather than the problem-solving tactics used by internal loci of control people.

CRITIQUE OF LOCUS OF CONTROL THEORY

In spite of its huge influence in the field of psychology, the locus of control concept has been criticized. In one noteworthy critique, the 1995 publication *Judgments of Responsibility: A Foundation for a Theory of Social Conduct* by Bernard Weiner, the author reasoned that the concept of “locus of control” was misleading and, in fact, that locus and control should be considered as two distinct dimensions involving causality—locus (internal versus external) and control (controllable versus uncontrollable). On this point Weiner held that a person could have an internal locus, and yet believe that she or he either was or was not in control; similarly people could hold external loci, and yet believe that they either were or were not in control. Thus, for example, efforts and ability are both internal in their loci, but effort is controllable and ability is uncontrollable. Weiner’s important point, therefore, is that there actually are two independent dimensions of causality, and that the Rotter theory may be incorrect in assuming that an internal locus always means that the person also is in control, and that an external locus always means that the person is not in control.

IMPLICATIONS

Locus of control may have been the most prominent new construct to appear in the interface of social, clinical, personality, and health psychology in the last three decades of the twentieth century. Loci of control scale scores have produced many robust correlations with outcome markers pertaining to psychological disorders, psychotherapy, school achievements, and physical health. Perhaps most importantly the locus of control concept solidified the importance of human expectancies in governing how people cope. As such locus of control facilitated the transition of psychology from an earlier emphasis on stimulus-response behaviorism to the twenty-first-century emphasis on cognitive and mental factors. Moreover locus of control has contributed to other theories such as learned helplessness, attributional biases, self-efficacy, hope, and optimism.

Logic

Logic is the study of persuasive reasoning. As such, it concerns arguments that successfully convey credibility from a set of premises to a conclusion. Given this broad definition, there are many possible avenues of discourse and logicians have studied everything from formal inference patterns, to the logic of causation, possibility and necessity, obligation, and inference to the best explanation. Nonetheless, formal deductive and inductive logic are the most historically significant branches of logic, even for the social sciences.

The discipline of logic evolved as a prominent branch of philosophy from the time of Aristotle and marks the first time in history that anyone began to systematize the forms of good reasoning. This systematization was of great benefit to philosophers as they attempted to know the universe of knowledge—covering both nature and human relations—on the basis of intuitive thought, rather than empirical analysis. As the sciences eventually pulled away from philosophy (first “natural philosophy” as it evolved into physics in about the seventeenth century, and then the social sciences arguably following in the eighteenth century, as they too learned that knowledge could be formulated on an empirical basis), it is only natural that they would develop their own methods of inquiry, separate from those of philosophers. Nonetheless, the special relationship of logic to the earliest forms of scientific analysis has survived to the twenty-first century, and has had great influence over the modes of inquiry in economics, history, sociology, anthropology, political science, and psychology, that make up the social sciences.

Logic is logic, whether it is applied to the social sciences, or any other field of inquiry. There is no special type of logic that is particularly suitable to the social sciences, just as there is not one for the natural sciences. The principles of valid reasoning are the same no matter what the subject, and are expressible in symbolic notation that is concerned only with the form, rather than the content, of what is uttered. To say “if I have a dollar then I have some money” is no different, logically, than to say, “If one is president of the United States then one is an American citizen.” The form of this type of “if, then” statement (P → Q) is known as a “conditional,” and, along with “not,” “or,” “and,” and “if and only if” (¬, ∨, &, ⇔), it forms the backbone of logical syntax. The idea that it is then possible to devise more complex statements using these connectives, to formulate premises and then to draw a conclusion, is to present the form of a “valid” argument in deductive logic, which is one where the conclusion follows necessarily from the premises. As long as the relationship between the premises and conclusion is a deductive one—which is to say that if the premises are true then the conclusion cannot help but be true—then the conclusion follows inevitably from the premises, and does not require any sort of empirical data to support it.

If it is raining then the streets will be wet.

It is raining.

Therefore, the streets will be wet.

This is, however, a long way from saying that such an argument is “sound” (that is, both valid and true) and it is here that the first limit of logic is reached in the social sciences, for as practitioners of an empirical discipline, social scientists are concerned to know whether an argument is sound (for instance whether its premises are true), and not just whether its form is valid. Therefore, we need to gather data in the world to assess this. No matter how powerful the principles of logic, in modern social scientific inquiry logic cannot provide the sole means for testing a theory, since logic is concerned not with truth, but with validity, yet the truth of a theory depends crucially on its conformity with actual experience. Pure logic can be done in an armchair, but science needs to go out into the world (if not for experiment, at least for observation).

In his or her search for causes, it is therefore incumbent upon social scientists to dig deeper into the subject, and find some way to assess whether a statement like “if one uses the death penalty then crime will drop” is true, and this is a tricky business, which deductive logic, at least, cannot adjudicate. However, there is another branch of logic that deals with “inductive” inferences that is much more conducive to empirical inquiry, and which some have felt represents the very type of reasoning that is used in science. In contrast to deduction—which deals with moving from general statements to the particular conclusions that follow from them—with induction one moves from particular statements to a general conclusion, somewhat as if one is gathering data points to see if they form a pattern. This resembles, at least ideally, the form of reasoning that a social scientist uses when he or she is searching for a general regularity. For example, if one were to argue that:

Kennedy’s tax cut in 1961 stimulated the economy
Reagan’s tax cut in 1981 stimulated the economy
Bush’s tax cut in 2003 stimulated the economy

Therefore, tax cuts always (usually, generally) stimulate the economy

one is engaging in a form of reasoning that is familiar to social scientists, who seek to make causal explanations and to formulate general theories based on historical evidence. The problem, however, is that this form of reasoning is...
not valid, as has famously been shown by the Scottish philosopher David Hume. Specifically, the above argument has a hidden assumption (common to all inductive arguments), which is to think that there is a relevant similarity between the future and the past. But this assumption does not always hold. Moreover, even if this assumption is borne out in some cases, it is important to recognize that there is a distinction to be made between “causation” and “correlation” in the social sciences, such that, no matter how solid one’s evidence may be, it is always possible that even the strongest correlation may represent only an accidental connection. Try as one might to obtain the sort of certainty that the “necessary connection” of deductive logic has provided, the social sciences have found this an elusive goal. This represents no particular flaw in the social sciences, for the natural sciences—or indeed any fact-based discipline—would also seem to suffer from this same difficulty.

Nonetheless, the social sciences have embraced the power of logic and have used it in various ways throughout their history to bolster their conclusions and to capitalize on the strengths of clear reasoning. The development of modern probability theory, and especially the invention of regression analysis in statistics, has been a very useful tool for social scientists to identify patterns in their data and to make sure that their hypotheses do not outrun them. The models of rationality that have been used throughout economics and political science—in particular those of rational choice and game theory—reflect another important way that the power of logic has had an impact on research design and model building in modern social science. In psychology, too, where experiments are designed to assess rational cognitive function by using thinly disguised logic games, one sees the influence of logic in social inquiry. Such reliance on logical modes of behavioral analysis, however, has come at a cost, for the new trend of “behavioral economics,” and the more general movement toward more realistic and experimental models in the social sciences, have revealed limitations in some of the classic theories in social science. Assumptions about “rational economic man,” for instance, may work ideally in our theoretical models, but break down when faced with the irrationality and fractured logic of everyday human experience that constitutes the subject matter of the social sciences.

In another avenue, however, the principles of logic have been unquestionably useful in the social sciences, and that is in research design, the formulation of hypotheses, and the analysis and synthesis of data and theory in social inquiry. Taking a page from the “scientific method” as is allegedly used in the natural sciences, some methodologists have argued that, as empirical disciplines, the social sciences should follow the “five-step method” of observation, hypothesis formulation, prediction, experiment (or learning from experience), and assessment. Despite the storied literature in the philosophy of science, provided by philosophers of science Karl Popper and Thomas Kuhn, that has rightly caused philosophers and others to rethink this simplistic model of scientific method, there is a nugget of truth in it for any discipline that cares to be empirical, which is to be ruthless about the comparison of one’s theory to the data. If a theory tells an individual to expect something, and one does not find it, then there is an inescapable problem for the theory. In a statement attributed to American physicist Richard Feynman, “It doesn’t matter how beautiful your theory is. If it doesn’t agree with experiment, it’s wrong.” This form of reasoning is directly related to the “conditional” in our earlier consideration of valid arguments, for it is trivially true that every conditional statement (if P, then Q) implies (indeed, is equivalent to) its “contrapositive” (if not Q, then not P). Thus, if one’s social scientific theory states, “If one is a thirteen-year-old boy then one has had an Oedipus Complex” and one finds a thirteen-year-old boy who has not had an Oedipus Complex, then the original theory is wrong. If a theory has even one exception, then it is not universally true and must either be discarded, or modified in some way to deal with this anomaly. As Popper demonstrated, here the power of logical certainty may be appreciated, since the contrapositive relationship is one of deductive, not inductive, reasoning and therefore may be relied upon as rock solid in its epistemological status.

The role of logic in the social sciences is a mixed one. As in the natural sciences one realizes that, if it is to explain the world, any empirical theory must go beyond the homilies of deductive reasoning and venture forth into the world of experience, with the chance of being wrong as the price of expressing a truth that is not trivial. Still, as we have seen, the power and benefits of logic have not been without value to the social sciences.

LOGIC, SYMBOLIC

Symbolic logic is sited at the intersection of philosophy, mathematics, linguistics, and computer science. It deals with the structure of reasoning and the formal features of information. Work in symbolic logic has almost exclusively treated the deductive validity of arguments: those arguments for which it is impossible for the premises to be true and the conclusion false. However, techniques from twentieth-century logic have found a place in the study of inductive or probabilistic reasoning, in which premises need not render their conclusions certain.

The historical roots of logic go back to the work of Aristotle (384–322 BCE), whose syllogistic reasoning was the standard account of the validity of arguments. Syllogistic reasoning treats arguments of a limited form: They have two premises and a single conclusion, and each judgment has a form like “all people are mortal,” “some Australian is poor,” or “no politician is popular.”

The discipline of symbolic logic exploded in complexity as techniques of algebra were applied to issues of logic in the work of George Boole (1815–1864), Augustus de Morgan (1806–1871), Charles Sanders Peirce (1839–1914), and Ernst Schröder (1841–1902) in the nineteenth century (see Ewald 1996). They applied the techniques of mathematics to represent propositions in arguments algebraically, treating the validity of arguments like equations in applied mathematics. This tradition survives in the work of contemporary algebraic logicians.

Connections between mathematics and logic developed into the twentieth century with the work of Gottlob Frege (1848–1925) and Bertrand Russell (1872–1970), who used techniques in logic to study mathematics. Their goals were to use the newfound precision in logical vocabulary to give detailed accounts of the structure of mathematical reasoning, in such a way as to clarify the definitions that are used, and to make fully explicit the commitments of mathematical reasoning. Russell and Alfred North Whitehead’s (1861–1947) Principia Mathematica (1912) is the apogee of this project of logicism.

With the development of these logical tools came the desire to use them in different fields. In the early part of the twentieth century, the logical positivists attempted to put all of science on a firm foundation by formalizing it: by showing how rich theoretical claims bear on the simple observations of experience. The best example of this is the project of Rudolf Carnap (1891–1970), who attempted to show how the logical structure of experience and physical, psychological, and social theory could be built up out of an elementary field of perception (Carnap 1967). This revival of empiricism was made possible by developments in logic, which allowed a richer repertoire of modes of construction or composition of conceptual content. On an Aristotelian picture, all judgments have a particularly simple form. The new logic of Frege and Russell was able to encompass much more complex kinds of logical structure, and so with it, theorists were able to attempt much more (Coffa 1991).

However, the work of the logical positivists is not the enduring success of the work in logic in the twentieth century. The radical empiricism of the logical positivists failed, not because of external criticism, but because logic itself is more subtle than the positivists had expected. We see this in the work of the two great logicians of the mid-twentieth century. Alfred Tarski (1902–1983) clarified our view of logic by showing that we can understand logic by means of describing the language of logic and the valid arguments by giving an account of proofs. However, we view logic by viewing the models of a logical language, and taking a valid argument as one for which there is no model in which the premises are true and the conclusion false. Tarski clarified the notion of a model and he showed how one could rigorously define the notion of truth in a language, relative to these models (Tarski 1956). The other great logician of the twentieth century, Kurt Gödel (1906–1978), showed that these two views of logic (proof theory and model theory) can agree. He showed that in the standard picture of logic, validity defined with proofs and validity defined by models agree (see von Heijenoort 1967).

Gödel’s most famous and most misunderstood result is his incompleteness theorem: This result showed that any account of proof for mathematical theories, such as arithmetic, must either be completely intractable (we can never list all of the rules of proof) or incomplete (it does not provide an answer for every mathematical proposition in the domain of a theory), or the theory is inconsistent. This result brought an end of the logicist program as applied to mathematics and the other sciences. We cannot view the truths of mathematics as the consequences of a particular theory, and the same holds for the other sciences (see von Heijenoort 1967).

Regardless, logic thrives. Proof theory and model theory are rich mathematical traditions, their techniques have been applied to many different domains of reasoning, and connections with linguistics and computer science have strengthened the discipline and brought it new applications.
Logical techniques are tools that may be used whenever it is important to understand the structure of the claims we make and the ways they bear upon each other. These tools have been applied in clarifying arguments and analyzing reasoning, and they feature centrally in the development of allied tools, such as statistical reasoning.

One contemporary debate over our understanding of logic also bears on the social sciences. We grant that using languages is a social phenomenon. How does the socially mediated fact of language-use relate to the structure of the information we are able to present with that use of language? Should we understand language as primarily representational, with inference valid when what is represented by the premises includes the representation of the conclusion, or should we see the social role of assertion in terms of its inferential relations? We may think of assertion as a social practice in which the logical relations of compatibility and reason-giving are fundamental. Once we can speak with each other, my assertions have a bearing on yours, and so logic finds its home in the social practice of expressing thought in word (Brandom 2000).

LOGISTIC REGRESSION

The logistic regression model is used when the dependent variable is categorical. A categorical variable is one whose numerical values serve only as labels distinguishing different categories. When a categorical variable has only two mutually exclusive outcomes, the binary logistic regression model is used. The logistic regression model had its origins in the biological sciences of the early twentieth century (Berkson 1944) but has subsequently found wide applicability in many areas of social science. The logistic regression model can be used for all data types but is most commonly used for cross-sectional data.

There are three different ways to derive or view the logistic regression model. In the first approach, one assumes that there is an unobserved or latent variable related to the observed outcome. For example, an individual’s decision to enter the labor force is made by comparing his or her unobserved reservation wage to the market wage. Only if the market wage exceeds the reservation wage does the individual enter the labor force. Secondly, the model can be viewed as a probability model for the dependent variable. Thirdly, the model can be derived from random utility theory or discrete choice model formulation (see McFadden 1974).

BINARY CASE

In the binary case, some event Y either occurs (Y = 1) or not (Y = 0). The linear probability regression model (LPM) is given by:

\[ Y = \beta X + \epsilon \]

where \( \beta = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \ldots + \beta_k X_k \) and \( \epsilon \) is the random error term.

The set of independent variables X affecting the event Y can be either continuous or categorical. The LPM model is problematic. First, the dependent variable Y is not constrained to lie between 0 and 1, and thus may produce nonsense probabilities. Also, the linear assumption holds that for every unit increase in X, the probability of Y occurring increases by the same amount. In many applications this assumption is not tenable. For example, the effect of an additional child on the probability of a female entering the labor force is assumed to be constant. It makes more sense to assume decreasing marginal effects of the number of children on the probability of a female entering the labor force. Also, the effect of changes in a specific X on the probability of Y does not depend on the other independent variables. In most applications this is also an unrealistic assumption. In the example above, the effect of an additional child on the probability of a female entering the labor force is assumed to be independent of, say, her husband’s income.

The logistic regression model was formulated to address these issues and can be written as:
The dependent variable is the log of the odds ratio of the event \( Y \) occurring or the log of the event \( Y \) occurring. Since the probability \( P \) is between 0 and 1, the odds ratio goes from 0 to \( \infty \) and the logit (an increasing function of \( P \)) goes from \( -\infty \) to \( +\infty \). Thus, the dependent variable in the logistic model is not constrained. The logistic model uses the cumulative logistic probability function to constrain the probability \( P \) to be between 0 and 1. In theory, any probability distribution can be used, however, the most popular choices include the normal, uniform, and the logistic distributions. The uniform distribution gives rise to the linear probability model, while the normal distribution gives rise to the probit model. In most binary applications, the logit and the probit models are very similar. Historically, for ease of computation, mathematical tractability, and ease of interpretability, the logistic model was the preferred choice. Solving for \( P \) in the logistic model, one obtains:

\[
(2) \quad \ln \left( \frac{P}{1 - P} \right) = X\beta + \epsilon
\]

where \( P \) = Probability \( (Y = 1) \).

The probability \( P \) is now nonlinear in \( X \). The effect of changes in \( X \) on the probability \( P \) are the smallest at the extreme points of the variable \( X \) or when \( P \) is close to 0 or 1, which makes sense in most applications. In addition, the effect of a unit change in a specific \( X \) on \( P \) now depends on all of the independent variables \( X \). The appropriate estimation method for the logistic model is the maximum likelihood estimation (MLE) method, since only \( Y \) and not \( P \) is observed. The MLE estimates are consistent and asymptotically normal and efficient. In addition, the standard likelihood ratio and Wald tests on the coefficients can be used. Since this is a nonlinear model, the marginal effect of \( X \) on \( Y \) can be estimated using either the point of means of the variables or by averaging the marginal effect over all of the sample observations. The standard measures of goodness of fit are overly pessimistic in this model, and other measures that are used include the count R-squared statistic, which gives the average correct predictions of the model over the two outcomes of \( Y \), or the pseudo R-squared statistic, which is the likelihood ratio statistic comparing the general model with the restricted model where all of the slope parameters \( (\beta_1 = \beta_2 = \ldots \beta_k = 0) \) are zero.

EXTENSIONS TO POLYCHOTOMOUS AND MULTIVARIABLE SITUATIONS

There are several approaches to modeling the polytomous (more than two categories) case, including the multinomial logistic model. Similarly, the multivariate logistic model may be used in the modeling of two or more choice variables. Other relevant distinctions are made among ordered, unordered, and sequential choice variables. An individual choosing among no work, part-time work, or full-time work is facing an ordered variable. The choice of mode of daily transportation by car, bus, train, or bicycle is an example of an unordered variable. The decision of a high school graduate to attend college or not and then, if college is chosen, to decide on a major program is an example of a sequential choice variable.

A problematic feature of the multinomial logistic model is the property of independence from irrelevant alternatives (IIA). The IIA property states that the choice between any two alternatives is made independent of the remaining alternatives. In situations where there are close substitutes in the set of alternatives, this property is unlikely to hold true. In the mode of transportation example, adding a blue bus to the choice set affects all of the probabilities assigned to each category. Thus, by adding enough buses of different colors, one can make the probability of driving a car arbitrarily small. One can formally test for IIA in the multinomial logistic model or use other models, such as the multinomial probit model, which does not have this property. Unlike the dichotomous single variable situation, there are now major differences between the logistic and probit models and many more types of models to choose from.

LOGIT REGRESSION

LOG-LINEAR MODELS
Within the realm of regression modeling, the term log-linear is used in two distinct ways. In the first case, it refers to nonlinear model specifications that—following a logarithmic transformation—become linear and can be estimated using tools available for the classical linear regression model. Most importantly, they can be estimated using ordinary least squares when assuming that the error terms are independent and normally distributed with mean 0 and equal variance \( \sigma^2 \). The multiplicative or double-log model and the exponential or semi-log model are two such nonlinear specifications. The multiplicative model takes on the form

\[
y_i = \beta_0 \prod_{j=1}^{m} x_{ij} \exp(\varepsilon_i),
\]

or, in its log-transformed equivalent,

\[
\ln y_i = \ln \beta_0 + \sum_{j=1}^{m} \beta_j \ln x_{ij} + \varepsilon_i, \quad \text{i.i.d. } N(0, \sigma^2),
\]

where \( \ln y_i \) is the dependent variable for observation \( i \), \( \ln x_{ij} \) is the \( j \)-th covariate or predictor variable, \( \beta_0, \ldots, \beta_m \) are parameters to be estimated and \( \varepsilon_i \) are the error terms. The multiplicative model implies that a 1 percent change in \( x \) (not \( \ln x \)) yields a \( \beta \) percent change in \( y \). It is frequently used to model large-scale traffic flows and migration flows. A well-known application in economics is the Cobb-Douglas production function that links output to capital and labor in a double-log specification, and where the parameters are the associated elasticities. The exponential or semi-log model takes on the form

\[
y_i = \beta_0 \exp\left(\sum_{j=1}^{m} \beta_j x_{ij} + \varepsilon_i\right),
\]

or, equivalently,

\[
\ln y_i = \ln \beta_0 + \sum_{j=1}^{m} \beta_j x_{ij} + \varepsilon_i, \quad \text{i.i.d. } N(0, \sigma^2).
\]

The exponential specification is most well-known for modeling unlimited and rapid population growth over time, where the dependent variable \( y \) represents the population, and time is the only covariate. The parameter \( \beta \) associated with time is the population growth rate, and a one-unit increase in time is expected to change the population by \( 100 \beta \) percent.

In the second case, the term log-linear model is used to refer to a particular class of generalized linear models (GLM), the so-called “Poisson models.” GLMs share a common mathematical structure in which the expected value of the dependent variable is functionally linked to a linear predictor. Unlike the multiplicative and exponential model, the Poisson regression model cannot be transformed into a classical linear regression model for which the link function is the identity function. Instead, the dependent variable is a count variable with Poisson-distributed non-negative integers as possible outcomes, and the link function connecting the expected value of \( Y \) with the linear predictor is the natural logarithm. For a Poisson-distributed random variable, the probability of observing \( k \) occurrences is

\[
P(Y = k) = \frac{\lambda^k e^{-\lambda}}{k!}
\]

where \( \lambda = E(Y) \) is the expected number of occurrences. A Poisson model stipulates a systematic relationship between the expected value and the predictor variables such that

\[
\lambda = E(Y) = \exp(\beta_0 + \sum_{j=1}^{m} \beta_j x_{ij})
\]

or, equivalently,

\[
\ln \lambda = \ln E(Y) = \beta_0 + \sum_{j=1}^{m} \beta_j x_{ij}
\]

for observations \( i = 1, 2, \ldots, n \).

The parameters \( \beta_j \) are estimated iteratively from the maximum-likelihood expression, typically using the Newton-Raphson estimation procedure. Today, most statistical software programs include estimation routines for Poisson regression models. Several measures, including the most frequently used \( \chi^2 \)-distributed log-likelihood ratio, provide an assessment of the goodness-of-fit of the estimated model to the observed data. The estimates of the parameters can be tested for significance using a \( z \)-distribution. A broad range of phenomena are suitable to be modeled in a Poisson regression setting. Characteristic of such phenomena is the comparatively low chance of occurrence per fixed unit of time (or space). This applies to, for example, counts of the number of automobile fatalities per month, the number of disease incidents per week, the number of species found in an ecosystem, and the frequency of severe weather events per year. The oldest and probably most cited application is the study by Ladislaus Josephovich von Bortkiewicz (1868–1931) in which he analyzed the probability of a soldier being killed through the kick of a horse. In his now-famous book on the laws of small numbers, von Bortkiewicz showed that rare events follow a Poisson distribution. The book appeared sixty-one years after the French mathematician Siméon Denis Poisson (1781–1840) had published his famous treaty on the limiting distribution—which is now rightfully named the “Poisson distribution”—of the binomial distribution when the probability of occurrence is small and the number of trials is large.

Whereas the origins of regression models go back to the German mathematician and physicist Johann Carl Friedrich Gauss (1777–1855) and the French mathematician Adrien-Marie Legendre (1752–1833), extensions
from the classical model to GLMs were made primarily over the last forty years. Credit goes to the seminal 1972 article by the statisticians John Ashworth Nelder and Robert William MacLagan Wedderburn. Nelder's 1983 book—coauthored with Peter McCullagh—still serves as the authoritative reference on GLMs. Recent refinements of Poisson models allow for relaxing the equidispersion assumption (i.e., for a Poisson-distributed random variable the expected value equals the variance). Advances also include mixed Poisson models in which, for instance, normally distributed random effects are added, or an abundance of zero-outcomes is accounted for in a so-called zero-inflated Poisson model. Although these advances make the log-linear regression model more flexible and suitable for a wider range of phenomena, their applicability needs to be thoroughly scrutinized, especially in situations where the linearity may be inappropriate, where the dispersion changes over time (or space), or where the observations are not independent.

LOMBARD STREET (BAGEHOT)

In the second half of the nineteenth century, world financial activity was centered in London. Within the city, the core of the financial district was Lombard Street, named after the bankers and financiers from northern Italy who centuries before had established their businesses there. In 1873, Walter Bagehot, editor of The Economist magazine, published a book that explained the workings of the London financial market. He titled it Lombard Street: A Description of the Money Market.

Lombard Street quickly became the main resource for understanding the workings of the London financial industry, replacing Henry Thornton's Enquiry into the Nature and Effects of the Paper Credit of Great Britain, published seven decades earlier in 1802. In Lombard Street, Bagehot briefly surveyed the origins of the London market and the reasons for its existence before undertaking a detailed description of the functions of a host of financial market participants, both public and private.

Lombard Street examines both the technical workings of the market and the government's policy actions within the market, as determined by the chancellor of the Exchequer and the directors of the Bank of England. It describes the activities of joint-stock banks, private banks, and bill brokers, all of which was of great interest to large numbers of contemporary readers. But the signal contribution of Lombard Street is Bagehot's discussion of how the Bank of England should behave toward other banks, especially when the money market was under stress.

The Bank Charter Act of 1844 had separated the Bank of England into an Issue Department, which issued bank notes backed by gold reserves, and a Banking Department, which was free to behave like an ordinary commercial bank. Critics of the Bank Act, including Bagehot's father-in-law James Wilson, founder of The Economist, argued throughout the 1850s and 1860s that the Bank's support of the money market during commercial crises was crucial and that the Bank of England should hold larger reserves of gold to meet the increased demand for gold during such periods. However, none of the critics developed a well-rounded case for the Bank to act as a central bank before Bagehot wrote.

Bagehot recognized that, though the Bank of England had no legal obligation to act as the nation's central bank, it in fact had done so since before 1800. Because the Bank kept the gold reserve for the entire economy, it had no choice but to act as a central bank. This meant that the Bank of England had to meet the banking system's liquidity needs during crises and that the Bank should act as lender of last resort when the increased demand to hold gold by individuals threatened the ability of solvent banks to meet their commitments.

Although the principle that the Bank of England would act as the banking system's lender of last resort was widely accepted after 1873, the British government implemented no legislation requiring the Bank to do so. Rather, the government assumed that the Bank would conduct its business appropriately. The Bank in fact did not hold larger gold reserves after 1873; in relation to the size of the banking system, the Bank's reserve shrank. The absence of any major crises over the next four decades prevents historians from knowing how the Bank of England would have behaved during a crisis.

LONELINESS
Social scientists agree that loneliness stems from the subjective experience of deficiencies in social relationships and that these deficiencies are unpleasant, aversive, and exceptionally common. Objectively deficient social relationships (i.e., social isolation) do not necessarily correspond with feeling lonely. Thus, it is common to appear alone but not feel lonely, and to feel lonely within a seemingly rich social relationship network. This potential paradox highlights an important distinction between quantitative and qualitative aspects of social relationships.

MODELS AND MEASUREMENT OF LONELINESS
Theoretical perspectives on loneliness differ concerning the nature of loneliness, whether loneliness stems from internal or situational causes, and where such causes occur developmentally. Psychoanalysts view loneliness as a pathological result of internal factors rooted in childhood. Sociologists view loneliness as a normative event stemming from societal influences that occur throughout development. From cognitive perspectives, loneliness occurs when people perceive discrepancies between their desired and actual patterns of relationships, with desired patterns stemming from previous relationships and comparisons of one’s own relationships to those of similar others (i.e., social comparison). Although different perspectives contribute uniquely to our understanding, the cognitive perspective serves as the dominant model for studying loneliness.

The measurement of loneliness depends inherently on theoretical conceptualizations of the construct. Unidimensional views of loneliness posit a common core of experience that varies in intensity regardless of the antecedents or causes of feeling lonely. Many unidimensional scales exist, but the UCLA Loneliness Scale is the most commonly used. This measure assesses loneliness via self-report without using the terms lonely or loneliness, thereby reducing social desirability influences. Extensive psychometric work indicates that it is a reliable and valid measure of loneliness.

Multidimensional measures involve assessments of perceived quality and quantity of social interaction across multiple domains such as romantic, friendship, family, and community relationships. Multidimensional views of loneliness have become more common in the research literature, spurring intensive psychometric work on these types of scales. Two multidimensional views of loneliness have received considerable research attention. The first breaks down loneliness into distinct components that reflect stable enduring traits or transitory states tied strongly to situation/context. Studies examining these components using specialized scales typically yield test-retest correlations that are higher (indicating greater stability) for measures assessing trait loneliness than for measures assessing state loneliness, suggesting that this distinction is valid. A second multidimensional view involves a distinction between social loneliness that results from a lack of relationships that provide a sense of belonging (e.g., friendships) and emotional loneliness that occurs when people lack relationships that foster deep connection or feelings of attachment (e.g., romantic relationships). Many scales designed to measure social and emotional loneliness exist, and research findings suggest that this distinction is also a valid one.

PERSONALITY, DEVELOPMENT, AND CONTEXT
Studies examining associations between personality characteristics and loneliness consistently show that extroverted people report less loneliness, whereas highly neurotic people often feel lonely. Low self-esteem, shyness, and pessimism also correspond to higher levels of loneliness. It remains unclear whether these personality traits lead to loneliness by limiting social contact and preventing the formation and maintenance of quality relationships, whether feeling lonely biases self-assessment of personality, or whether personality predisposes one to develop few relationships, and the subsequent lack of relationships reciprocally influences one’s personality. There remains a need for continued research that delineates causal paths among personality characteristics and loneliness.

Most children understand that being alone does not necessarily mean one is lonely, and that people can feel lonely when they do not appear to be alone. Adolescents experience more loneliness than do other individuals due to necessary restructuring of social groups to include friendships and other social relationships outside of the family during transitions to elementary, junior high, and high school. Family environments also influence the development of relationships in that children surrounded
by parental conflict exhibit social anxiety and avoidance that contribute to loneliness.

Young adults face many contextual events, such as moving out of the home or going away to college, that require the development of new social ties. During these transitions, interpersonal difficulties may hinder the development of new social relationships, leaving one feeling lonely. Shy people who maintained a few high-quality relationships during high school may suddenly feel very lonely away at college when their shyness interferes with opportunities to make new friends. Although these types of life transitions often foster feelings of temporary loneliness that subside over time for most people, some individuals remain chronically lonely, suggesting that interpersonal difficulties or personality characteristics contribute to feelings of loneliness across the life span.

During adulthood, contextual transitions including college graduations and the establishment of careers present challenges to existing social networks and the need to form new relationships. New obstacles include individualistic or competitive work environments that make the formation and maintenance of satisfying relationships difficult. As adults, people place less emphasis on friendships than on intimate or romantic relationships. Although intimate relationships provide protection from loneliness, relationship quality is vital as adults in strained or unsatisfying relationships often report feeling lonely.

Elderly individuals face a number of challenges to maintaining their social networks, including the loss of relationships with coworkers through retirement, reduced contact with adult children, and the deaths of spouses or friends. Decreased functional mobility, cognitive impairment, and physical illness strain existing relationships and impede the establishment of new relationships. Despite these challenges, the elderly are less lonely on average than are college students, and increases in loneliness occur only among individuals eighty years and older. Married men and women report less loneliness than do elderly widows and widowers and men and women who are divorced or never married. Spouses in elderly couples provide functional support in addition to companionship and emotional connection, suggesting multiple ways in which marriage serves to protect against feelings of loneliness. For those without spouses, friendships with similar others provide more protection against loneliness than do relationships with adult children and neighbors.

**LONELINESS, HEALTH, AND COPING**

Consistent links between loneliness, life satisfaction, and anxiety exist, and loneliness is associated with depression independently of age, gender, physical health, cognitive impairment, network size, and social activity involvement. In addition, loneliness influences well-being and feelings of hopelessness independently of associations with social isolation and perceived social support. Loneliness also relates to physical health, as evidenced by its consistent associations with alcohol abuse, admission of the elderly to nursing homes, suicide, and mortality.

Although loneliness uniquely influences physical health, potential causes for these connections have received varying degrees of support. One view posits that loneliness affects health through maladaptive behaviors including smoking, drinking, poor exercise habits, and substandard dietary practices; however, lonely and nonlonely people rarely differ in the frequency of such behaviors. Alternative models argue that loneliness influences physical reactions to stress including cardiovascular activation, cortisol production, immunocompetence deficiencies, and sleep disruptions that link directly to development of cardiovascular disease, susceptibility to disease and infection, and diminished restorative processes that maintain overall resilience. Emerging findings provide initial support for these links, suggesting promising avenues for future research.

Strategies for coping with loneliness include changing actual relationships, expectations about relationships, or reducing the importance of relationships. Attempts to change one’s social relationships are active coping strategies wherein feelings of loneliness motivate people to form new relationship ties. Changing expectations about social relationships involves cognitive restructuring of how people view the social relationships of others. Attempts to reduce the importance of social relationships or engage in diversionary activities are passive coping strategies that often do little to alleviate loneliness.

Researchers have begun to explore the success of intervention programs in reducing feelings of loneliness, and promising findings have emerged. Social skills training for children and young adults provide the tools needed to effectively initiate, develop, and maintain satisfying social relationships. College orientation, mentoring, and buddy-pairing programs provide social contact with similar others in hopes of fostering relationship development during a transitional period when loneliness is quite common. Finally, interventions that effectively reduce loneliness among older adults target specific groups (e.g., divorcées or widows) and provide social contact opportunities with similar others as well as information that is useful for maintaining established social relationships.

LONELY CROWD, THE

The Lonely Crowd, published in 1950, was written by sociologist David Riesman (1909–2002) in collaboration with Reuel Denney (1913–1995) and Nathan Glazer (b. 1923). Initially expected to sell only several thousand copies, this study of the links between social structure and national character has sold over 1.4 million copies from its initial publication, making it the best-selling sociology book in the United States.

Writing in the post–World War II (1939–1945) period, Riesman sought to understand what kinds of character structures were being encouraged by the social institutions of modern society, including capitalist corporations, political institutions, and the mass media. He proposed three different character types. The tradition-directed type was the product of unchanging societies in which social patterns were rooted in the past. The traditional character was rigid, insular, and not open to innovation. The development of industrial society, however, required a new character type. The nineteenth century saw the rise of what Riesman called the inner-directed type. This character received its essential structure in its youth, through strong family and community socialization. Unlike the traditional type, the inner-directed person could change and develop, but only following the direction of his or her inner gyroscope, whose essential pattern had been determined in youth.

Riesman argued that in the mid-twentieth century the inner-directed type was being replaced by a new character type. Modern organizations demanded people who took their cues from what other people expected of them. These other-directed individuals used their social radar, rather than an inner gyroscope, to guide their values and actions. They preferred to be loved rather than esteemed. Their character was not shaped primarily by family or religion, but rather was strongly influenced by peer culture and the mass media.

When it was first published, The Lonely Crowd received many critical reviews, but nonetheless resonated widely in American society. Readers could appreciate the social changes within twentieth-century American society; they experienced firsthand the growing power of corporations and the greater presence of the media, including television, which was then in its infancy. They could—or thought they could—identify inner- and other-directed people among their relatives and friends, and detect differences between generations. Riesman himself, of course, proposed these terms as ideal types, with most people in modern society combining elements of the different character types.

The popularity of the book was also due to the clear, declarative writing style that artfully mixed interview data with evidence culled from magazines, movies, and even children’s books. The Lonely Crowd was a jargon-free, wide-ranging analysis of the sort that sociology has largely since abandoned. To some extent, it is a period piece. Many of its assertions have since proved wrong, most notably a demographic hypothesis that tied the rate of population growth to national character type, a hypothesis that Riesman himself abandoned in the 1969 edition. But other hypotheses about the tenuous balance between the social conformity demanded by society and desires for autonomy among individuals continue to demand attention, even as the paradoxical phrase, “the lonely crowd,” has entered into public discourse as an image of anomie within affluent society.

LONG PERIOD ANALYSIS
The forces that operate on economic processes are manifold and complex. In the eighteenth century philosophers of the Scottish and French Enlightenments, influenced in part by developments in the natural sciences (notably Newtonian mechanics) sought to identify the mechanisms that regulate social life. With the displacement of feudalism by a nascent market system as the dominant mode of material provisioning, an obvious question arose concerning whether the interactions of countless self-interested economic actors could generate benign social outcomes. Thomas Hobbes, in *Leviathan* (1651), had argued that a powerful state was necessary to contain the destructive potential of human nature. Mercantilist policies were partly grounded in the view that the market is an unreliable guarantor of the commonwealth’s prosperity. In *The Fable of the Bees* (1724) Bernard Mandeville suggested that sentiments and behaviors commonly regarded as vices—envy, cupidity, gluttony, lust, pride—underpinned national economic well-being by stimulating demand for services and for the products of industry. Mandeville, who delighted in poking respectable opinion in the eye, had put his finger on a distinctive feature of capitalism: that markets to a significant degree generate order out of the self-interested behavior of atomistic agents. But he provided no scientific account of how markets coordinate the decisions of individual economic actors.

Market outcomes are not always benign. But capitalism is not chaotic. Somehow commodities get produced using sophisticated technologies that require the cooperation of many workers performing specialized tasks at different locations. The commodities are produced not in random quantities but in amounts that roughly match the demand for them. Resources get channeled from declining industries into expanding sectors. The process can be messy, and occasionally it falters. Yet the system manages to reproduce itself, to grow and to undergo structural and technological transformation. It is able to do all this without the intervention of a conscious coordinating hand.

ADAM SMITH’S FOUNDATION
Adam Smith is credited with providing the first systematic account of how markets generate order. His argument owes a good deal to Richard Cantillon’s *Essai sur la nature du commerce en général* (1755) and to Anne Robert Jacques Turgot’s *Réflexions sur la formation et la distribution des richesses* (1769–1770). Smith’s argument is set out in book 1, chap. 7 (“Of the Natural and Market Price of Commodities”) of the *Wealth of Nations* (1776). The chapter outlines a method of analysis that grounded theoretical economics until the middle of the twentieth century. That method, long period analysis, starts from the premise that in a market economy competition manifests itself as a tendency for profit rates to equalize across all lines of production. Smith drew a distinction between the natural price of a good and the market price. The natural price, which later generations of economists called the long period equilibrium price, is the price that would, if it obtained, be just sufficient to cover the commodity’s cost of production, where cost is understood to include a normal rate of return for the owners of the capital invested in the enterprise. The market price of a good is the price that is actually observed. Smith argued that the natural price is a center of gravitation toward which market prices are pushed by the dominant and persistent forces operating in a market economy. Accidental and temporary circumstances may cause market prices to rise above or fall below the natural price, but “they are constantly tending towards it” (Smith 1776, book 1, chap. 7, p. 65).

The mechanism that pushes market prices toward their long period equilibrium levels is what coordinates the self-interested activity of the economy’s participants. We may reasonably suppose that the owners of capital will prefer to invest it in enterprises that earn high rates of return rather than in enterprises that earn low rates of return. That is why, from the economist’s point of view, a normal return on investment is an element of cost: The market prices of a good must, on average, be sufficient not only to cover labor costs, the costs of raw materials, and the cost of depreciation of physical equipment; if the price
Long Period Analysis

is not high enough to give the owners of capital the same rate of return they could obtain in other lines of production, the owners will eventually transfer their capital to those other sectors. As capital flows into the high return sectors, the output of those sectors increases, and as the supply of those commodities becomes more abundant, their market prices fall, lowering the rate of profit in those sectors. In the sectors that are experiencing an outflow of capital, outputs decline, causing market prices and hence rates of return to rise. The overall tendency is for rates of return to converge, provided there are no impediments to the movement of capital, and for prices to move toward their natural levels, which are consistent with equalization of profit rates. (If there are barriers to the movement of capital, such as patents or monopolistic control of particular necessary resources, the mechanism nevertheless operates, but the long period position will then be characterized by profit rate differentials.) The flow of capital in pursuit of its highest return brings the structural composition of production capacity into line with the composition of demand. It is also the principal mechanism by which economic systems absorb new technologies and adjust to major changes in the regulatory or institutional framework or in the availability of natural resources. It is what Smith meant by the “invisible hand” (1776, book 4, chap. 2, p. 477).

CLASSICAL ECONOMICS AND NEOCLASSICAL THEORY

The adjustments just described take place over long stretches of time, as capital goods wear out and are replaced by new and usually different ones; hence the label “long period method.” This method proved immensely useful for analyzing the determination of relative prices and the closely connected question of what determines the distribution of income among social classes. But the method makes no presumption about how the variables of the economy are determined. Historically two broad approaches to the explanation of prices and distribution may be identified—the surplus approach of Karl Marx and the classical political economists, in particular Smith and David Ricardo, and neoclassical supply and demand theory. The theories differ with respect to the data they treat as parametric in explaining prices. The classical economists and Marx took the social product, the real wage, and the technology of production as given in their attempts to explain relative prices and the rate of profit. Perhaps the feature that distinguishes the approach most starkly from modern economics is its conception of the real wage as a socially and institutionally conditioned variable. (A later variation of the theory, associated with Piero Sraffa, treats the profit rate as the parametric distribution variable.) The marginalist or neoclassical theory that emerged in the last decades of the nineteenth century explains prices and incomes in terms of the interaction of price-elastic demand and supply functions derived from a somewhat different set of data: the preferences of economic agents, the economy's endowment of productive resources and the distribution of that endowment among the members of society, and the technology of production. The two frameworks arrive at different explanations of prices and distribution, but until the middle of the twentieth century they utilized the same long period method, in which market forces are understood to move the economy toward a fully adjusted position characterized by a uniform rate or profit across sectors.

In the twentieth century, however, mainstream neoclassical economics underwent a shift in method, in which long period analysis gradually gave way to models of temporary or intertemporal general equilibrium. These models drop the requirement that equilibrium be characterized by a uniform profit rate and instead define equilibrium entirely in terms of market clearing—the absence of excess demand. (Intertemporal equilibrium models assume the existence of complete futures markets—markets existing in the present, which reflect agents' beliefs about the probability distributions of all future contingent states of nature; in temporary equilibrium models, equilibrium occurs when agents' short-term expectations about prices and quantities are fulfilled.) The emergence and then ascendance of these approaches appear to be related to two considerations. First, they may reflect an attempt to avoid capital theoretic problems that are evident in long period versions of the neoclassical theory (the same problems may well be present in intertemporal and temporary equilibrium models, but in such models they are less transparent). Second, these models were in part motivated by a desire to move beyond the static analysis of the long period approach and to depict the patterns of change that every actual economy undergoes over time. But the models are themselves limited in their ability to depict actual economic processes: Complete futures markets do not exist, and short-period equilibria can explain the temporal sequence of prices and outputs only if the equilibria are actually established by market forces. A distinct advantage of the long period method is that the equilibrium values established by the theory need not be achieved in reality: The explanatory value of long period models lies in the supposition that the equilibrium positions established by such models are centers of gravitation for the actually observed values of the variable, which may deviate from the values predicted by the theory for any number of accidental or random causes.

The long period method has been the target of criticism as well. Among institutionalist economists there is a long tradition of skepticism toward equilibrium analysis. More troublesome perhaps is the fact that the stability of...
long period positions is notoriously difficult to establish in both the surplus approach and neoclassical applications of the method. The stability of an equilibrium position refers to the position’s status as a center of gravitation: Under what is it reasonable to suppose that an accidental disturbance of the system will set in motion a set of adjustments that move the economy back toward the long period position? If the conditions necessary to ensure a return to the equilibrium are excessively strict, we cannot take it for granted that the long period position is a center of gravitation, and in that case the method’s claims to capture real-world processes are weakened.

CLASSICAL AND NEOCLASSICAL PERSPECTIVES

The term was explicitly used for the first time in the works of the Cambridge economist Alfred Marshall (1842–1924), who detailed a concept of long-run equilibrium that became broadly accepted and used in the scientific community. Implicitly, the classical economists of the eighteenth century, Adam Smith (1723–1790) and David Ricardo (1772–1823), already used the concept of a long-run equilibrium, as did Karl Marx (1818–1883) after them. The former focused attention on so-called “normal” or long-period positions of the economy in conditions of free competition and the corresponding system of “natural values” and a uniform rate of profits. These natural values guarantee the payment of wages, profits, and rents so that no extra profits occur. In contrast, “market values” are the observed prices that are influenced by all sorts of factors, both systematic and accidental, persistent and temporary. Market values do not necessarily converge to their natural values but are considered to gravitate around their natural levels. Marx had a similar view on the long-run position of the economy. The classical economists determined the rate of profits and relative prices in terms of given levels of output, given technical alternatives, and a given wage rate (or share of wages).

The neoclassical economists of the nineteenth century and early twentieth century used a related methodology. Their theories attempted to determine prices, income distribution, and quantities simultaneously in terms of given endowments, technical alternatives, and preferences. Their works led to the elaboration of general equilibrium analysis, which, in contrast to partial equilibrium analysis, focuses on the economic system as a whole. Among the neoclassical economists, Marshall in Principles of Economics (1890) made a distinction between four different types of equilibria: temporary, short run, long run, and secular equilibrium. In temporary or very short run equilibrium, supply is fixed, and the price is solely determined by demand. In the short run, supply itself is not fixed, but the production is constrained by a given plant and equipment. As a consequence, productive capacity is given in a short run. In the long run, supply can adjust perfectly to demand via an adjustment of productive capacity within the prevailing production technology. Finally, in the secular or very long run, technical knowledge may change. Although neoclassical authors developed the tools for handling short-run problems, the long-run analysis remained dominant.

EXTENSIONS AND CRITICISM

John Maynard Keynes (1883–1946) called for focused attention on short-run problems with his witticism in A Tract on Monetary Reform: “In the long run we are all dead.”

LONG RUN

The term long run entered economic analysis as economists started considering different time horizons in their analyses. All the consequences of economic events may not occur immediately, nor may they all happen at the same time. The concepts of long and short run were thus introduced in order to cope with these problems. In a long-run context, all consequences are assumed to be finished, whereas in the short run only some effects are taken into account.
(Keynes 1923, p. 65). An investigation of the impact of effective demand on output, given productive capacities, is at the center of Keynes's magnum opus *The General Theory of Employment, Interest, and Money* (1936). His conclusion is that the demand side of the economy is of crucial importance not only in the short run but in the long run as well. This argument is studied in terms of income and employment multipliers, which originally were suggested by the British economist Richard Kahn (1905–1989), who augmented Marshall's distinction of long and short run with a classification as regards cost. In the short period, firms face fixed costs, and windfall profits or losses might occur. By contrast, costs are entirely variable in the long run because all factors of production become flexible, at least in principle. Companies can freely enter and exit industries, which leads to a uniform profit rate throughout the economy. Contrary to previous authors, the U.S. economist Milton Friedman (1912–2006) defined the long period with regard to adaptive expectations. In numerous works he investigated the effects of monetary policies and discovered that they were moderate in the short run and practically nil in the long. He maintained that there is no long-term trade-off between inflation and unemployment because of the influence of expectations regarding inflation on the behavior of forward-looking agents. Exogenous shocks can only affect the economy in the short run, whereas they have no influence in the long run. In contrast to Keynes, Friedman stated that the long run is determined entirely by supply-side conditions and effective demand does not matter. An even more radical point of view, based on the theory of rational expectations, was established by the U.S. economist Robert Lucas (b. 1937). In his contributions to the theory of endogenous growth, he argued that the economy would converge to a balanced path, irrespective of short-run perturbations. This balanced path is considered to be a close approximation to any actual development, and thus the attention should focus on it.

The different types of long-run equilibria mentioned are also known as “stationary equilibria,” “steady states,” and “intertemporal equilibria.” The relative importance of either long-run or short-run analysis has varied considerably over time. Whereas classical and neoclassical economists predominantly treated long-run problems, Keynes drew attention to the short run. In correspondence to the different problems at hand, the methods applied varied vastly, from micro to macro and from static to dynamic. A convincing unification of the long- and short-run points of view is not yet in sight. The time horizon and therefore the distinction between short and long run seem to remain crucial in economics.

**LONG WAVES**

Since the beginning of the twentieth century, observers of the world economy have been analyzing long-term regularities associated with the behavior of the leading economies. Statistical analysis of more than a century of price behaviors and output series in the United States and Britain led Nikolai Kondratiev (1892–1938), a Russian Marxist economist, to conclude in the 1920s that boom-and-bust long-wave cycles exist and that their duration is between fifty and sixty years. The study of key growth indicators of industrial and world output between 1826 and 1968 by Ernest Mandel (1995) found that the periods 1826 to 1847, 1848 to 1873, 1874 to 1893, 1894 to 1913, 1914 to 1939, and 1940 to 1967 were marked with striking fluctuation in the average rates of growth, with ups and downs between successive long waves ranging from 50 to 100 percent. His analysis provided strong evidence of long waves in capitalist development.
In the 1930s, the economist Joseph Schumpeter (1883–1950) endorsed the long-wave concept as a reasonable explanation of macroeconomic activity, and he named the pattern, after Kondratieff, K-waves. Schumpeter’s own work focused on the clustering of innovations during the phase of economic depression (the Winter phase). He used the terms “swarms of technological progress” and “gales of creative destruction” to describe this phase. Innovations are hypothesized to cluster during the Winter phase because only then do firms resort to the highly risky strategy of introducing basic, new-to-the-world innovations. This phase is thought to be a key driver of new technological paradigms or structural shifts in the economy. Societies’ adjustments to the basic innovations take the form of S-shaped growth or learning life cycles and are accomplished in the latter three phases (Spring, Summer, and Autumn) of the long waves. Here, firms extract profit from the dominant technologies, rather than seeking new innovations.

Long waves are most often written about during periods of economic downturns and are viewed as a way out of an impending crisis. They receive considerably less press during times of prosperity because the long-wave theory would suggest the less popular hypothesis, namely, that the good times will not last.

ORIGIN
Long waves are not thought to be unique to the nineteenth and twentieth centuries. Some authors have traced them back in Europe over five hundred years, others have identified nineteen such waves dating back to printing and paper in 930, and others assert that they go back at least five thousand years. This entry, however, discusses only the last five such waves (between 1800 and 2025), which represent the industrialization of modern economies. Each appears to have a dominant technology driver, but technology is only one part of a much broader innovation system that is responsible for the long-wave phases. The transportation systems, communication modes, primary energy sources, manufacturing processes, corporate organizational structures, and public administration approaches appear to be unique to particular waves and provide the all-important context for the full depth and breadth of the technology to flourish for each long wave. Thus, long waves arise from the clustering of fundamental innovations that initiate technological revolution and that in turn create leading commercial and industrial sectors. (See Table 1.)

THEORY
According to Schumpeter, long waves are caused by the demand for solutions to new problems, and innovative firms supply these solutions. Each new wave has its own unique innovative character, its own identity, but it is composed of four common phases. The four phases, often described as seasons, are thought of as dramatic mood changes of the economy that can be anticipated by individuals and can influence their actions. As discussed previously, the Winter (depression) phase is characterized by a collapse of the price system, which forces the economy into a sharp period of retrenchment. A three-year collapse is followed by a fifteen-year deflationary work-out period where risky innovation takes place.

The Spring phase (the inflationary growth phase) requires approximately twenty-five years to complete and is characterized by wealth accumulation, new innovation, great upheaval and displacement, and significant social unrest. The exponential growth reaches its limit, inefficiencies build up in the system, and a Summer (stagflation, recession) phase is entered and lasts for twenty to

twenty-five years. The Autumn (deflationary growth, plateau) phase of seven to ten years follows with rapid rises in prices, selective industry growth, a strong feeling of affluence, and a general isolationist mood in the citizenry. Interest in long-wave theory waned in the 1940s, 1950s, and 1960s (and again in the 1990s) because predicting a downturn during boom times was not fashionable, but the theory resurfaced when a new group, known as neo-Shumpeterians, sought to explain the economic downturns of the 1960s, 1970s, and 1980s.

**EMPIRICAL SUPPORT**

Kondratieff was the first to use regression procedures to reveal long waves in economic time series data, and Jay Forrester’s computer simulation of the macroeconomic process also reproduced long-wave patterns of roughly fifty years. While subsequent econometric research using time series data and equilibrium assumptions do not find unambiguous support for them, long-wave supporters argue that methodologies based on equilibrium assumptions are flawed because today’s economy is structurally unstable and evolutionary in nature. They suggest long waves need to be measured by observations of physical events associated with the economy, like innovations, rather than traditional economic measures.

Robert Metz’s study (2005) of over fifteen thousand innovations during the 1750–1991 period found innovation clusters peaking in 1840, 1890, 1935, and 1986, followed by an upswing in economic growth eighteen years later, thereby confirming the depression trigger innovation hypothesis. At the beginning of a long-wave cycle, innovations usually center around one country and a few breakthrough technologies; however, the creation of a new techno-economic system, as shown in Table 1, requires sustained innovations in the related, complementary areas.

**POLICY SIGNIFICANCE**

If, as asserted above, long waves are a consequence of the inner dynamics of economic growth, then policy makers can put forth prescriptions during different phases of the economic cycle. For example, a government’s policy would have its greatest impact on innovation during the Winter phase, for entrepreneurs need to be encouraged most then. During the Spring phase, governments have to keep a check on inflation to ensure that the economy does not overheat. During the Summer phase of stagflation or recession, the government can offer policies to stimulate the economy. The last prescriptive area is during the Autumn phase, when government policies should be most concerned about controlling inflation. Another interesting finding is that international political economists have studied the relationship between long waves and war and find that wars and revolutions are much more likely to occur during the economic-upswing phase.

**LEGITIMATE CONCERNS**

Some economists argue that long waves have less validity in a post–World War II (1939–1945) economy given the monetary and fiscal tools available to governments. They cite Federal Reserve Chairman Alan Greenspan’s providing of massive liquidity after the dot-com bust of 2000 to prevent a Kondratieff Winter. Wave supporters counterargue that the resulting debt from this policy has become unsustainable and only temporarily postponed the pending Winter phase for a few years. As evidenced by the above arguments, the timing of each phase is critical to policymakers and economists. Unfortunately, long-wave theory lacks precision in this domain, particularly in the area of explaining the downturn at the end of the prosperity phase.

**LOOKING-GLASS EFFECT**

The looking-glass effect, or the looking-glass self, may be defined as people’s conceptualization of their own views of
self, based on how they perceive that others view them. The concept has provided a captivating theoretical springboard for social scientists from a broad variety of disciplines. Sociologists and psychologists have historically focused on this effect more than researchers in other fields, however, because of the effect’s inherent focus on both society and the individual as critical shaping forces in the development of human identity.

The term looking-glass effect was coined by Charles Horton Cooley, a social psychologist, in his 1902 treatise entitled Human Nature and the Social Order. Cooley’s assertion that people derive their attitudes about themselves based on how others perceive them drew on earlier works by William James and inspired the work of George Herbert Mead, founder of the school of thought known as symbolic interactionism.

Central to the existence of the looking-glass self is the presence of a social audience; to learn about themselves, people require others to provide self-relevant information. Gordon Gallup’s work with chimpanzees highlighted the necessity of a history of social interaction to the existence of self-knowledge (Gallup 1977). In a series of investigations, Gallup and his colleagues demonstrated that chimpanzees that were reared in isolation from other chimpanzees responded to their reflections in a mirror in a very different fashion from their socially informed, nonisolated counterparts. Whereas nonisolates recognized themselves in a mirror and evidenced recognition of a researcher-induced change in their physical appearance, isolates never demonstrated knowledge that they were viewing a reflection of themselves in the mirror. Without a prior history of information about themselves gleaned from interactions with other chimpanzees, isolates were seemingly devoid of a concept of self.

Though Cooley’s original notion of the looking-glass self implied that people imagine how others must view them and, as a result, develop self-attitudes based on these imagined evaluations by others, it did not detail whether or not these imagined evaluations were accurate. It assumed, rather, that people should be able effectively to learn about themselves from social feedback from others. Later work revealed, however, that people’s self-evaluations may not be rooted in others’ actual evaluations but in people’s beliefs about how others evaluate them (Shrauger and Schoeneman 1979). So, in effect, people could misperceive others’ attitudes about themselves and, correspondingly, report self-attitudes that did not align with others’ real evaluations.

Findings that the looking-glass effect may not provide people with accurate self-evaluations challenged the informative utility of the effect but paved the way for future investigations concerning it. Much of this work has revealed that people’s own feelings of self-worth, or self-esteem, play a role in how they think that others view them. People who have more positive self-evaluations tend to believe that others view them positively as well. Likewise, people who view themselves negatively are more likely to believe that others view them in the same negative light. As a result, a more nuanced definition of the looking-glass effect is people’s evaluations of themselves based on their own self-attitudes and their perceptions, which are influenced by these self-attitudes, of how others view them (Tice and Wallace 2003).

LOSS FUNCTIONS
The loss function (or cost function) is a crucial ingredient in all optimizing problems, such as statistical decision theory, policymaking, estimation, forecasting, learning, classification, financial investment, and so on. The discussion here will be limited to the use of loss functions in econometrics, particularly in time series forecasting.

When a forecast \( f_{t+h} \) of a variable \( Y_{t+h} \) is made at time \( t \) for \( h \) periods ahead, the loss (or cost) will arise if a forecast turns out to be different from the actual value. The loss function of the forecast error \( e_{t+h} = Y_{t+h} - f_{t+h} \) is denoted as \( c(Y_{t+h}-f_{t+h}) \). The loss function can depend on the time of prediction, and so it can be \( c_t(Y_{t+h}-f_{t+h}) \). If the loss function does not change with time and does not depend on the value of the variable \( Y_{t+h} \), the loss can be
written simply as a function of the error only, \( c_{t+h}(Y_{t+h}, f_t, h) = c(e_{t+h}) \).

Clive Granger (1999) discusses the following required properties for a loss function: (1) \( c(0) = 0 \) (no error and no loss); (2) \( \min c(e) = 0\), so that \( c(e) \geq 0 \); and (3) \( c(e) \) is monotonically nondecreasing as \( e \) moves away from zero so that \( c(e_1) \geq c(e_2) \) if \( e_1 > e_2 > 0 \) and if \( e_1 < e_2 < 0 \).

When \( c_1(e) \), \( c_2(e) \) are both loss functions, Granger (1999) shows that further examples of loss functions can be generated: \( c(e) = ac_1(e) + bc_2(e), a \geq 0, b \geq 0 \) will be a loss function; \( c(e) = c_1(e)^a c_2(e)^b, a > 0, b > 0 \) will be a loss function; and \( c(e) = 1(e > 0)c_1(e) + 1(e < 0)c_2(e) \) will be a loss function. If \( b(\cdot) \) is a positive monotonic nondecreasing function with \( b(0) \) finite, then \( c(e) = b(c_1(e)) - b(0) \) is a loss function.

**LOSS FUNCTIONS AND RISK**

Granger (2002) notes that an expected loss (a risk measure) of financial return \( Y_t \) that has a conditional predictive distribution \( F_t(y) \equiv Pr(Y_t \leq y|I_t) \) with \( Y_t \in I_t \) may be written as

\[
\mathbb{E}[c(e)] = A_1 \int_0^y (y - f^0_t) dF_t(y) + A_2 \int_y^{\infty} (y - f^0_t) dF_t(y),
\]

with \( A_1, A_2 \) both \( > 0 \) and some \( \theta > 0 \). Considering the symmetric case \( A_1 = A_2 \), one has a class of volatility measures \( V_\theta = \mathbb{E}[|y - f_\theta|^0] \), which includes the variance with \( \theta = 2 \), and mean absolute deviation with \( \theta = 1 \).

Zhuanxin Ding, Clive Granger, and Robert Engle (1993) study the time series and distributional properties of these measures empirically and show that the absolute deviations are found to have some particular properties, such as the longest memory. Granger remarks that given that the financial returns are known to come from a long-tail distribution, \( \theta = 1 \) may be more preferable.

Another problem raised by Granger is how to choose optimal \( L_p \)-norm in empirical works, to minimize \( \mathbb{E}[|\varepsilon|^p] \) for some \( p \) to estimate the regression model \( Y_t = X_t \beta + \varepsilon_t \). The asymptotic covariance matrix of \( \hat{\beta} \) depends on \( p \), the most appropriate value of \( p \) can be chosen to minimize the covariance matrix. In particular, Granger (2002) refers to a trio of papers (Nyquist 1983; Money et al. 1982; and Harter 1977) that find that the optimal \( p = 1 \) from Laplace and Cauchy distribution, \( p = 2 \) for Gaussian, and \( p = \infty \) (min/max estimator) for a rectangular distribution.

Granger (2002) also notes that in terms of the kurtosis \( \kappa \), H. L. Harter (1977) suggests using \( p = 1 \) for \( \kappa > 3.8 \), \( p = 2 \) for \( 2.2 \leq \kappa \leq 3.8 \), and \( p = 3 \) for \( \kappa < 2.2 \). In finance, the kurtosis of returns can be thought of as being well over 4, so \( p = 1 \) is preferred.

We consider some variant loss functions with \( \theta = 1, 2 \) below.

**LOSS FUNCTIONS AND REGRESSION FUNCTIONS**

Optimal forecasting of a time series model depends extensively on the specification of the loss function. Symmetric quadratic loss function is the most prevalent in applications due to its simplicity. The optimal forecast under quadratic loss is simply the conditional mean, but an asymmetric loss function implies a more complicated forecast that depends on the distribution of the forecast error as well as the loss function itself (Granger 1999), as the expected loss function is formulated with the expectation taken with respect to the conditional distribution. Specification of the loss function defines the model under consideration.

Consider a stochastic process \( Z_t \equiv (Y_t, X_t)' \), where \( Y_t \) is the variable of interest and \( X_t \) is a vector of other variables. Suppose there are \( T + 1 \) (\( \equiv R + P \)) observations. We use the observations available at time \( t \), \( R \leq t < T + 1 \), to generate \( P \) forecasts using each model. For each time \( t \) in the prediction period, we use either a rolling sample \( \{Z_{t-R+1}, \ldots, Z_t\} \) of size \( R \) or the whole past sample \( \{Z_1, \ldots, Z_t\} \) to estimate model parameters \( \beta^{(j)} \). We can then generate a sequence of one-step-ahead forecasts \( \{f(Z_t, \beta^{(j)})\}_{j=1}^J \).

Suppose that there is a decision maker who takes a one-step point forecast \( f_{t+1} \equiv f(Z_t, \beta) \) of \( Y_{t+1} \) and uses it in some relevant decision. The one-step forecast error \( e_{t+1} \equiv Y_{t+1} - f_{t+1} \) will result in a cost of \( c(e_{t+1}) \), where the function \( c(e) \) will increase as \( e \) increases in size, but not necessarily symmetrically or continuously. The optimal forecast \( f_{t+1} \) will be chosen to produce the forecast errors that minimize the expected loss

\[
\min_{f_{t+1}} \int_{-\infty}^{\infty} c(y - f_{t+1}) dF_t(y),
\]

where \( F_t(y) \equiv Pr(Y_{t+1} \leq y|I_t) \) is the conditional distribution function, with \( I_t \) being some proper information set at time \( t \) that includes \( Z_{t-j}, j \geq 0 \). The corresponding optimal forecast error will be \( e_{t+1} = Y_{t+1} - f_{t+1} \).

Then the optimal forecast would satisfy

\[
\frac{\partial}{\partial f_{t+1}} \int_{-\infty}^{\infty} c(y - f_{t+1}) dF_t(y) = 0.
\]

When we interchange the operations of differentiation and integration,
the generalized forecast error, $g_{t+1} \equiv \frac{\partial}{\partial f_t} c(Y_{t+1} - f_t)$, forms the condition of forecast optimality:

$$H_0: g_{t+1} \equiv \frac{\partial}{\partial f_t} c(Y_{t+1} - f_t) = 0 \ a.s.$$  

that is, a martingale difference (MD) property of the generalized forecast error. This forms the optimality condition of the forecasts and gives an appropriate regression function corresponding to the specified loss function $c(\cdot)$.

To see this, consider the following two examples. First, when the loss function is the squared error loss

$$c(\cdot) = (\cdot)^2,$$

the generalized forecast error will be

$$g_{t+1} \equiv \frac{\partial}{\partial f_t} c(Y_{t+1} - f_t) = -2Y_{t+1} f_t$$

and thus $\mathbb{E}(g_{t+1} | I_t) = 0 \ a.s.$, which implies that the optimal forecast

$$f_{t+1}^* = \mathbb{E}(Y_{t+1} | I_t)$$

is the conditional mean. Next, when the loss is the check function, $c(\cdot) = |\cdot| - \theta \cdot \mathbb{I}(\cdot < \theta)$, $\theta > 0$, the optimal forecast $f_{t+1}^*$, for given $\theta \in (0, 1)$, minimizing

$$\min_{f_t} \mathbb{E}[c(Y_{t+1} - f_t) | I_t]$$

can be shown to satisfy

$$\mathbb{E}[\alpha - 1(Y_{t+1} < f_{t+1}^*) | I_t] = 0 \ a.s.$$  

Hence, $g_{t+1} \equiv \alpha - 1(Y_{t+1} < f_{t+1}^*)$ is the generalized forecast error. Therefore,

$$\alpha = \mathbb{E}[\alpha - 1(Y_{t+1} < f_{t+1}^*) | I_t] = Pr(Y_{t+1} < f_{t+1}^* | I_t),$$

and the optimal forecast $f_{t+1}^* = \alpha(Y_{t+1} | I_t)$ is the conditional $\alpha$-quantile.

**LOSS FUNCTIONS FOR ASYMMETRY**

Granger (1999) notes that it is implausible to use the same loss function for forecasting $Y_{t+h}$ and for forecasting $h_{t+1} = b(Y_{t+h})$ where $b(\cdot)$ is some function, such as the log or the square, if one is interested in forecasting volatility. Suppose the loss functions $c_1(\cdot)$, $c_2(\cdot)$ are used for forecasting $Y_{t+h}$ and for forecasting $b(Y_{t+h})$, respectively. Let $e_{t+1} \equiv Y_{t+1} - f_{t+1}$ result in a cost of $c_1(e_{t+1})$, for which the optimal forecast $f_{t+1}^*$ will be chosen from $\min_{f_t} \int_{0}^{e_{t+1}} c_1(y - f_{t+1}) \, dF(y)$, where $F(y) \equiv Pr(Y_{t+1} \leq y | I_t)$. Let $\varepsilon_{t+1} \equiv h_{t+1} - h_{t+1}^*$ will result in a cost of $c_2(\varepsilon_{t+1})$, for which the optimal forecast $h_{t+1}^*$ will be chosen from $\min_{h_t} \int_{0}^{\varepsilon_{t+1}} c_2(h - h_{t+1}) \, dH(h)$, where $H(h) \equiv Pr(h_{t+1} \leq h | I_t)$. Then the optimal forecasts for $Y$ and $h$ would respectively satisfy

$$\int_{-\infty}^{\infty} \frac{\partial}{\partial f_t} c(Y - f_t) \, dF(y) = 0,$$

$$\int_{-\infty}^{\infty} \frac{\partial}{\partial h_t} c(h - h_t) \, dH(h) = 0.$$  

It is easy to see that the optimality condition for $f_{t+1}$ does not imply the optimality condition for $h_{t+1}$ in general. Under some strong conditions on the functional forms of the transformation $b(\cdot)$ and of the two loss functions $c_1(\cdot)$, $c_2(\cdot)$, the above two conditions may coincide. Granger (1999) remarks that it would be strange behavior to use the same loss function for $Y$ and $b(Y)$. This awaits further analysis in future research.

**LOSS FUNCTIONS FOR TRANSFORMATIONS**

Granger (1999) notes that it is overwhelming majority of forecast work uses the cost function $c(\cdot) = \alpha^2 \cdot \theta$ for the evaluation of a forecast is the symmetric quadratic function. Negative and positive forecast errors of the same magnitude have the same loss. This functional form is assumed because mathematically it is very tractable, but from an economic point of view, it is not very realistic. For a given information set and under a quadratic loss, the optimal forecast is the conditional mean of the variable under study. The choice of the loss function is fundamental to the construction of an optimal forecast. For asymmetric loss functions, the optimal forecast can be more complicated as it will depend not only on the choice of the loss function but also on the characteristics of the probability density function of the forecast error (Granger 1999).

As Granger (1999) notes, the overwhelming majority of forecast work uses the cost function $c(\cdot) = \alpha^2 \cdot \theta$, $\alpha > 0$, largely for mathematical convenience. Asymmetric loss function is often relevant. A few examples from Granger (1999) follow. The cost of arriving ten minutes early at the airport is quite different from arriving ten minutes late. The cost of having a computer that is 10 percent too small for a task is different from the computer being 10 percent too big. The loss of booking a lecture room that has ten seats too many for your class is different from that of a room that has ten seats too few. In dam construction, an underestimate of the peak water level is usually much more serious than an overestimate (Zellner 1986).

There are some commonly used asymmetric loss functions. The check loss function $c(\cdot) = [\alpha - 1(\cdot < \theta)] \cdot (\cdot - \theta)$, or $c(\cdot) \equiv [\alpha - 1(\cdot < 0)] \cdot \theta$, makes the optimal predictor $f$ the conditional quantile. The check loss function is also known as the **tick function** or **lil-lin loss**. The asymmetric quadratic loss $c(\cdot) \equiv [\alpha - 1(\cdot < 0)] \cdot \theta$, can also be considered. A value of $\alpha = 0.5$ gives the symmetric squared error loss.
A particularly interesting asymmetric loss is the *linex function* of Hal Varian (1975), which takes the form
\[ c_1(e, \alpha) = \exp(\alpha e) - \alpha e - 1, \]
where \( \alpha \) is a scalar that controls the aversion toward either positive \((\alpha > 0)\) or negative \((\alpha < 0)\) forecast errors. The linex function is differentiable. If \( \alpha > 0 \), the linex is exponential for \( e > 0 \) and linear for \( e < 0 \). If \( \alpha < 0 \), the linex is exponential for \( e < 0 \) and linear for \( e > 0 \). To make the linex more flexible, it can be modified to the double linex loss function by
\[ c(e) = c_1(e, \alpha) + c_1(e, -\beta), \quad \alpha > 0, \beta > 0, \]
which is exponential for all values of \( e \) (Granger 1999). When \( \alpha = \beta \), it becomes the symmetric double linex loss function.

**LOSS FUNCTIONS FOR FORECASTING FINANCIAL RETURNS**

Some simple examples of the loss function for evaluating the forecasted values of financial returns are the out-of-sample mean of the following loss functions studied in Yongmiao Hong and Tae-Hwy Lee (2003): the squared error loss \( L(y, f) = (y - f)^2 \); absolute error loss \( L(y, f) = |y - f| \); trading return \( L(y, f) = -\text{sign}(f) \cdot y \) (when \( y \) is a financial asset return); and the correct direction \( L(y, \hat{y}) = -\text{sign}(f) \cdot \text{sign}(y) \), where \( \text{sign}(x) = 1(x > 0) - 1(x < 0) \) and \( 1(\cdot) \) takes the value of 1 if the statement in the parentheses is true and 0 otherwise. The negative signs in the latter two are to make them the loss to minimize (rather than to maximize). The out-of-sample mean of these loss functions are the mean squared forecast errors (MSFE), mean absolute forecast errors (MAFE), mean forecast trading returns (MFTR), and mean correct forecast directions (MCFD):

\[
\begin{align*}
\text{MSFE} &= P^{-1} \sum_{t=R}^{T} (Y_{t+1} - f_{t,1})^2, \\
\text{MAFE} &= P^{-1} \sum_{t=R}^{T} |Y_{t+1} - f_{t,1}|, \\
\text{MFTR} &= -P^{-1} \sum_{t=R}^{T} \text{sign}(f_{t,1}) \cdot Y_{t+1}, \\
\text{MCFD} &= -P^{-1} \sum_{t=R}^{T} 1(\text{sign}(f_{t,1}) \cdot \text{sign}(Y_{t+1}) > 0). 
\end{align*}
\]

These loss functions may further incorporate issues such as interest differentials, transaction costs, and market depth. Because the investors are ultimately trying to maximize profits rather than minimize forecast errors, MSFE and MAFE may not be the most appropriate evaluation criteria. Granger (1999) emphasizes the importance of model evaluation using economic measures such as MFTR rather than statistical criteria such as MSFE and MAPE. Note that MFTR for the buy-and-hold trading strategy with \( \text{sign}(f_{t,1}) = 1 \) is the unconditional mean return of an asset because \( \text{MFTR}^{\text{Buy&Hold}} = -P^T \sum_{t=R}^{T} Y_{t+1} \to -\mu \) in probability as \( P \to \infty \), where \( \mu \equiv \mathbb{E}(Y) \). MCFD is closely associated with an economic measure as it relates to market timing. Mutual fund managers, for example, can adjust investment portfolios in a timely manner if they can predict the directions of changes, thus earning a return higher than the market average.

**LOSS FUNCTIONS FOR ESTIMATION AND EVALUATION**

When the forecast is based on an econometric model, to the construction of the forecast, a model needs to be estimated. Inconsistent choices of loss functions in estimation and forecasting are often observed. We may choose a symmetric quadratic objective function to estimate the parameters of the model, but the evaluation of the model-based forecast may be based on an asymmetric loss function. This logical inconsistency is not inconsequential for tests assessing the predictive ability of the forecasts. The error introduced by parameter estimation affects the uncertainty of the forecast and, consequently, any test based on it.

However, in applications, it is often the case that the loss function used for estimation of a model is different from the one(s) used in the evaluation of the model. This logical inconsistency can have significant consequences with regard to comparison of predictive ability of competing models. The uncertainty associated with parameter estimation may result in invalid inference of predictive ability (West 1996). When the objective function in estimation is the same as the loss function in forecasting, the effect of parameter estimation vanishes. If one believes that a particular criteria should be used to evaluate forecasts, then it may also be used at the estimation stage of the modeling process. Gloria González-Rivera, Tae-Hwy Lee, and Emre Yoldas (2007) show this in the context of the VaR model of RiskMetrics, which provides a set of tools to measure market risk and eventually forecast the value-at-risk (VaR) of a portfolio of financial assets. A VaR is a quantile return. RiskMetrics offers a prime example in which the loss function of the forecaster is very well defined. They point out that a VaR is a quantile, and thus the check loss function can be the objective function to estimate the parameters of the RiskMetrics model.
LOSS FUNCTION FOR BINARY FORECAST AND MAXIMUM SCORE

Given a series \{Y_t\}, consider the binary variable \( G_{t+1} \equiv 1(Y_{t+1} > 0) \). We consider the asymmetric risk function to discuss a binary prediction. To define the asymmetric risk with \( A_1 \neq A_2 \) and \( p = 1 \), we consider the binary decision problem of Clive Granger and Hashem Pesaran (2000b), and Tae-Hwy Lee and Yang Yang (2006) with the following 2 x 2 payoff or utility matrix:

<table>
<thead>
<tr>
<th>Utility</th>
<th>( G_{t+1} = 1 )</th>
<th>( G_{t+1} = 0 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( G_{t+1} = 1 )</td>
<td>( u_{11} )</td>
<td>( u_{01} )</td>
</tr>
<tr>
<td>( G_{t+1} = 0 )</td>
<td>( u_{10} )</td>
<td>( u_{00} )</td>
</tr>
</tbody>
</table>

where \( u_j \) is the utility when \( G_{t+1}(X_t) = j \) is predicted and \( G_{t+1}(X_t) = \hat{i} \) is realized (\( i, j = 1, 2 \)). Assume \( u_{11} > u_{10} \) and \( u_{00} > u_{01} \), and \( u_j \) are constant over time; \( (u_{11} - u_{10}) > 0 \) is the utility gain from taking correct forecast when \( G_{t+1}(X_t) = 1 \); and \( (u_{00} - u_{01}) > 0 \) is the utility gain from taking correct forecast when \( G_{t+1}(X_t) = 0 \). Denote

\[
\pi(X_t) \equiv \mathbb{E}_{Y_{t+1}}(G_{t+1}|X_t) = \Pr(G_{t+1} = 1|X_t).
\]

The expected utility of \( G_{t+1}(X_t) = 1 \) is \( u_{11}\pi(X_t) + u_{01}(1 - \pi(X_t)) \), and the expected utility of \( G_{t+1}(X_t) = 0 \) is \( u_{10}\pi(X_t) + u_{00}(1 - \pi(X_t)) \). Hence, to maximize utility, conditional on the values of \( X_t \), the prediction \( G_{t+1}(X_t) = 1 \) will be made if

\[
u_{11}\pi(X_t) + u_{01}(1 - \pi(X_t)) > u_{10}\pi(X_t) + u_{00}(1 - \pi(X_t)),\]

or

\[
\pi(X_t) > \frac{(u_{00} - u_{01})}{(u_{11} - u_{10}) + (u_{00} - u_{01})} = 1 - \alpha.
\]

By making a correct prediction, our net utility gain is \( (u_{00} - u_{01}) \) when \( G_{t+1} = 0 \), and \( (u_{11} - u_{10}) \) when \( G_{t+1} = 1 \). Put another way, our opportunity cost (in the sense that you lose the gain) of a wrong prediction is \( (u_{00} - u_{01}) \) when \( G_{t+1} = 0 \) and \( (u_{11} - u_{10}) \) when \( G_{t+1} = 1 \). Since a multiple of a utility function represents the same preference, \( (1 - \alpha) \) can be viewed as the utility gain from correct prediction when \( G_{t+1} = 0 \), or the opportunity cost of a false alert. Similarly,

\[
\alpha = \frac{(u_{11} - u_{10})}{(u_{11} - u_{10}) + (u_{00} - u_{01})}
\]

can be treated as the utility gain from correct prediction when \( G_{t+1} = 1 \) is realized, or the opportunity cost of a failure-to-alert. We thus can define a cost function \( c(\hat{e}_{t+1}) \) with \( \hat{e}_{t+1} = G_{t+1} - G_{t+1}(X_t) \):

<table>
<thead>
<tr>
<th>Cost</th>
<th>( G_{t+1} = 1 )</th>
<th>( G_{t+1} = 0 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( G_{t+1}(X_t) = 1 )</td>
<td>0</td>
<td>1 - ( \alpha )</td>
</tr>
<tr>
<td>( G_{t+1}(X_t) = 0 )</td>
<td>( \alpha )</td>
<td>0</td>
</tr>
</tbody>
</table>

That is,

\[
c(\hat{e}_{t+1}) = \begin{cases} 
\alpha & \text{if } \hat{e}_{t+1} = 1 \\
1 - \alpha & \text{if } \hat{e}_{t+1} = -1, \\
0 & \text{if } \hat{e}_{t+1} = 0
\end{cases}
\]

which can be equivalently written as \( c(\hat{e}_{t+1}) = \rho(\hat{e}_{t+1}) \), where \( \rho(e) \equiv \left[ \alpha - 1(e < 0)\right] \) is the check function. Hence, the optimal binary predictor \( G_{t+1}(X_t) = 1(\pi(X) > 1 - \alpha) \) maximizing the expected utility minimizes the expected cost \( \mathbb{E}\rho(\hat{e}_{t+1})|X_t \).

The optimal binary prediction that minimizes \( \mathbb{E}_{Y_{t+1}}(\rho(\hat{e}_{t+1})|X_t) \) is the conditional \( \alpha \)-quantile of \( G_{t+1} \), denoted as

\[
G_{t+1}(X_t) = Q_\alpha(G_{t+1}|X_t) = \arg\min \mathbb{E}_{Y_{t+1}}(\rho(\hat{e}_{t+1})|X_t)|_{G_{t+1}(X_t)}.
\]

This is a maximum score problem of Charles Manski (1975).

Also, as noted by James Powell (1986), using the fact that for any monotonic function \( h() \), \( Q_h(b(Y_{t+1}|X_t)) = b(Q_h(Y_{t+1}|X_t)) \), which follows immediately from observing that \( \Pr(Y_{t+1} < b) = \Pr[h(Y_{t+1}) < b(\rho)|X_t] \), and noting that the indicator function is monotonic, \( Q_h(G_{t+1}|X_t) = Q_h(1(Y_{t+1} > 0)|X_t) = 1(Q_h(Y_{t+1}|X_t) > 0) \). Hence,

\[
Q_h(G_{t+1}|X_t) = 1(Q_h(Y_{t+1}|X_t) > 0),
\]

where \( Q_h(Y_{t+1}|X_t) \) is the \( \alpha \)-quantile function of \( Y_{t+1} \) conditional on \( X_t \). Note that \( Q_h(G_{t+1}|X_t) = \arg\min \mathbb{E}_{Y_{t+1}}(\rho(\hat{e}_{t+1})|X_t) \) with \( \hat{e}_{t+1} = G_{t+1} - G_{t+1}(X_t) \), and \( Q_h(Y_{t+1}|X_t) = \arg\min \mathbb{E}_{Y_{t+1}}(\rho(\hat{e}_{t+1})|X_t) \) with \( \hat{e}_{t+1} = Y_{t+1} - Q_h(Y_{t+1}|X_t) \). Therefore, the optimal binary prediction can be made from binary quantile regression for \( G_{t+1} \). Binary prediction can also be made from a binary quantile function of the \( \alpha \)-quantile for \( Y_{t+1} \).

LOSS FUNCTIONS FOR PROBABILITY FORECASTS

Francis Diebold and Glenn Rudebusch (1989) consider the probability forecasts for business-cycle turning points. To measure the accuracy of predicted probabilities, that is, the average distance between the predicted probabilities and observed realization (as measured by a zero-one dummy variable). Suppose we have time series of \( P \) probability forecast \( \{p_t\}_{t=R+1}^T \), where \( p_t \) is the probability of the occurrence of a turning point at date \( t \). Let \( \{d_t\}_{t=R+1}^T \) be the
corresponding realization with \( d_t = 1 \) if a business-cycle turning point (or any defined event) occurs in period \( t \) and \( d_t = 0 \) otherwise. The loss function analogous to the squared error is Brier’s score based on the quadratic probability score (QPS):

\[
QPS = P^{-1} \sum_{t=R}^{T} 2(p_t - d_t)^2.
\]

The QPS ranges from 0 to 2, with 0 for perfect accuracy. As noted by Diebold and Rudebusch (1989), the use of the symmetric loss function may not be appropriate, as a forecaster may be penalized more heavily for missing a call (making a Type II error) than for signaling a false alarm (making a Type I error). Another loss function is given by the log probability score (LPS)

\[
LPS = -P^{-1} \sum_{t=R}^{T} \ln \left( p_t d_t (1 - p_t) (1 - d_t) \right),
\]

which is similar to the loss for the interval forecast. Major mistakes are penalized more heavily under LPS than under QPS. Further loss functions are discussed in Diebold and Rudebusch (1989).

Another loss function useful in this context is the Kuipers score (KS), which is defined by

\[
KS = \text{Hit Rate} - \text{False Alarm Rate},
\]

where the hit rate is the fraction of the bad events that were correctly predicted as good events (power, or 1—probability of Type II error), and the false alarm rate is the fraction of good events that have been incorrectly predicted as bad events (probability of Type I error).

**LOSS FUNCTION FOR INTERVAL FORECASTS**

Suppose \( Y_t \) is a stationary series. Let the one-period-ahead conditional interval forecast made at time \( t \) from a model be denoted as

\[
J_{t+1}(\alpha) = (L_{t+1}(\alpha), U_{t+1}(\alpha)), \ t = R, \ldots, T,
\]

where \( L_{t+1}(\alpha) \) and \( U_{t+1}(\alpha) \) are the lower and upper limits of the ex ante interval forecast for time \( t + 1 \) made at time \( t \) with the coverage probability \( \alpha \). Define the indicator variable \( X_{t+1}(\alpha) = 1[Y_{t+1} \in J_{t+1}(\alpha)] \). The sequence \( \{X_{t+1}(\alpha)\}_{t=R}^{T} \) is IID Bernoulli (\( \alpha \)). The optimal interval forecast would satisfy \( E(X_{t+1}(\alpha)|I_t) = \alpha \), so that \( \{X_{t+1}(\alpha) - \alpha\} \) will be an MD. A better model has a larger expected Bernoulli log-likelihood

\[
\alpha X_{t+1}(\alpha) (1 - \alpha)^{1 - X_{t+1}(\alpha)}.
\]

Hence, we can choose a model for interval forecasts with the smallest out-of-sample mean of the negative predictive log-likelihood defined by

\[
-P^{-1} \sum_{t=R}^{T} \ln \left( \alpha X_{t+1}(\alpha) (1 - \alpha)^{1 - X_{t+1}(\alpha)} \right).
\]

**LOSS FUNCTION FOR DENSITY FORECASTS**

Consider a financial return series \( \{y_t\}_{t=1}^{T} \). This observed data on a univariate series is a realization of a stochastic process \( Y^\tau \equiv \{Y_t; \Omega \rightarrow \mathbb{R}, \tau = 1, 2, \ldots, T\} \) on a complete probability space \( (\Omega, \mathcal{B}_T, P_T^0) \), where \( \Omega = \mathbb{R}^T \equiv x^T_\tau \equiv \mathbb{R} \) and \( \mathcal{B}_T = B(\mathbb{R}^T) \) is the Borel \( \sigma \)-field generated by the open sets of \( \mathbb{R}^T \), and the joint probability measure \( P_T^0(B) \equiv P_0(y^T \in B), B \in B(\mathbb{R}^T) \) completely describes the stochastic process. A sample of size \( T \) is denoted as \( y^T \equiv (y_1, \ldots, y_T) \).

Let \( \sigma \)-finite measure \( \nu^T \) on \( B(\mathbb{R}^T) \) be given. Assume \( P_T^0(B) \) is absolutely continuous with respect to \( \nu^T \) for all \( T = 1, 2, \ldots, \) so that there exists a measurable Radon-Nikodým density \( g^T(y^T) = dP_T^0/d\nu^T \), unique up to a set of zero-measure \( -\nu^T \).

Following Halbert White (1994), we define a probability model \( P \) as a collection of distinct probability measures on the measurable space \( (\Omega, \mathcal{B}_T) \). A probability model \( P \) is said to be correctly specified for \( Y^\tau \) if \( P \) contains \( P_T^0 \). Our goal is to evaluate and compare a set of parametric probability models \( \{P^k_T\} \), where \( P^k_T(B) \equiv P^k_T(y^T \in B) \). Suppose there exists a measurable Radon-Nikodým density \( f^T(\hat{y}^T) = dP^0_T/d\nu^T \) for each \( \theta \in \Theta \), where \( \theta \) is a finite-dimensional vector of parameters and is assumed to be identified on \( \Theta \), a compact subset of \( \mathbb{R}^k \) (see White 1994, Theorem 2.6).

In the context of forecasting, instead of the joint density \( g^T(y^T) \), we consider forecasting the conditional density of \( Y_T \), given the information \( \mathcal{F}_{t-1} \) generated by \( Y_{t-1} \). Let \( \varphi(y) = \varphi(y|\mathcal{F}_{t-1}) = \varphi(y|\mathcal{F}_{t-2}) \) for \( t = 2, 3, \ldots \) and \( \varphi(y_1) \equiv \varphi(y_1|\mathcal{F}_{t-1}) \equiv \varphi(y_1) = g(y_1) \). Thus the goal is to forecast the (true, unknown) conditional density \( \varphi(y) \).

For this, we use a one-step-ahead conditional density forecast model \( \psi(y_t; \theta) \equiv \psi(y_t|\mathcal{F}_{t-1}; \theta) = f(y_t|f^{-1}(y_{t-1})) \) for \( t = 2, 3, \ldots \) and \( \psi(y_1) \equiv \psi(y_1|\mathcal{F}_{t-1}) \equiv f(y_1) = f(y_1). \) If \( \psi(y_t; \theta) \) almost surely for some \( \theta \in \Theta \), then the one-step-ahead density forecast is correctly specified, and it is said to be optimal because it dominates all other density forecasts for any loss functions as discussed in the previous section (see Granger and Pesaran 2000a, 2000b; Diebold et al. 1998; Granger 1999).

In practice, it is rarely the case that we can find an optimal model. As it is very likely that “the true distribution is in fact too complicated to be represented by a simple mathematical function” (Sawa 1978), all the models proposed by different researchers can be possibly misspecified and thereby we regard each model as an approximation of the truth. Our task is then to investigate which
density forecast model can approximate the true conditional density most closely. We have to first define a metric to measure the distance of a given model to the truth, and then compare different models in terms of this distance.

The adequacy of a density forecast model can be measured by the conditional Kullback-Leibler information criterion (KLIK) (1951) divergence measure between two conditional densities,

$$\| I(\phi; \psi, \theta) = \mathbb{E}_{\gamma_t}[\ln \psi_{(y_t)} - \ln \psi_{(y_t^*)}], $$

where the expectation is with respect to the true conditional density $\psi_{(\mathcal{X}_{t-1})}$, $\mathbb{E}_{\gamma_t}[\psi_{(y_t)}|\mathcal{X}_{t-1}] < \infty$, and $\mathbb{E}_{\gamma_t}[\psi_{(y_t)}|\mathcal{X}_{t-1}, \theta] < \infty$. Following White (1994), we define the distance between a density model and the true density as the minimum of the KLIK

$$\| I_{(\phi; \psi, \theta^*; \gamma)} = \min_{\theta} \| I(\phi; \psi, \theta),$$

where $\theta^* = \arg \min_{\theta} \| I(\phi; \psi, \theta)$ is the pseudotrust value of $\theta$ (Sawa 1978). We assume that $\theta^* \in \Theta$ is an interior point of $\Theta$. The smaller this distance is, the closer the density forecast $\psi_{(\mathcal{X}_{t-1}; \theta^*)}$ is to the true density $\psi_{(\mathcal{X}_{t-1})}$.

However, $I_{(\phi; \psi; \theta^*, \gamma)}$ is unknown since $\theta^*$ is not observable. We need to estimate $\theta^*$. If our purpose is to compare the out-of-sample predictive abilities among competing density forecast models, we split the data into two parts, one for estimation and the other for out-of-sample validation. At each period $t$ in the out-of-sample period ($t = R + 1, ..., T$), we estimate the unknown parameter vector $\theta^*_{(t-1)}$ and denote the estimate as $\hat{\theta}_{(t-1)}$. Using $[\hat{\theta}_{(t-1)}, ..., \hat{\theta}_{(R+1)}]^T$, we can obtain the out-of-sample estimate of $I_{(\phi; \psi; \theta^*, \gamma)}$ by

$$\| I_{p(\phi; \psi)} = \frac{1}{P} \sum_{t = R+1}^{T} \ln [\phi_{(y_t)}|\psi_{(y_t)}, \hat{\theta}_{(t-1)}],$$

where $P = T - R$ is the size of the out-of-sample period. Note that

$$\| I_{p(\phi; \psi)} = \frac{1}{P} \sum_{t = R+1}^{T} \ln \left[\frac{\phi_{(y_t)}}{\psi_{(y_t)}}, \hat{\theta}_{(t-1)} \right] + \frac{1}{P} \sum_{t = R+1}^{T} \ln \left[\frac{\psi_{(y_t^*)}}{\psi_{(y_t)}}, \hat{\theta}_{(t-1)} \right],$$

where the first term in $\| I_{p(\phi; \psi)}$ measures model uncertainty (the distance between the optimal density $\phi_{(y_t)}$ and the model $\psi_{(y_t; \theta^*)}$), and the second term measures parameter estimation uncertainty due to the distance between $\theta^*$ and $\hat{\theta}_{(t-1)}$.

Since the KLIK measure takes on a smaller value when a model is closer to the truth, we can regard it as a loss function and use $\| I_{p(\phi; \psi)}$ to formulate the loss-differential. The out-of-sample average of the loss-differential between model 1 and model 2 is

$$\| I_{p(\phi; \psi)} - \| I_{p(\phi; \psi^2)} = \frac{1}{P} \sum_{t = R+1}^{T} \ln \left[\frac{\psi_{(y_t)}|\theta^2_{(t-1)}}{\psi_{(y_t)|\theta^1_{(t-1)}}} \right],$$

which is the ratio of the two predictive log-likelihood functions. With treating model 1 as a benchmark model (for model selection) or as the model under the null hypothesis (for hypothesis testing), $\| I_{p(\phi; \psi)} - \| I_{p(\phi; \psi^2)}$ can be considered as a loss function to minimize. To sum up, the KLIK differential can serve as a loss function for density forecast evaluation as discussed in Yong Bao, Tae-Hwy Lee, and Burak Saltoglu (2007).

**LOSS FUNCTIONS FOR VOLATILITY FORECASTS**

Gloria González-Rivera, Tae-Hwy Lee, and Santosh Mishra (2004) analyze the predictive performance of various volatility models for stock returns. To compare the performance, they choose loss functions for which volatility estimation is of paramount importance. They deal with two economic loss functions (an option pricing function and a utility function) and two statistical loss functions (the check loss for a value-at-risk calculation and a predictive likelihood function of the conditional variance).

**LOSS FUNCTIONS FOR TESTING GRANGER-CAUSALITY**

In time series forecasting, a concept of causality is due to Granger (1969), who defined it in terms of conditional distribution. Tae-Hwy Lee and Weiping Yang (2007) use loss functions to test for Granger-causality in conditional mean, in conditional distribution, and in conditional quantiles. The causal relationship between money and income (output) has been an important topic that has been extensively studied. However, those empirical studies are almost entirely on Granger-causality in the conditional mean. Compared to conditional mean, conditional quantiles give a broader picture of a variable in various scenarios. Lee and Yang (2007) explore whether forecasting the conditional quantile of output growth may be improved using money. They compare the check (tick) loss functions of the quantile forecasts of output growth with and without using the past information on money growth, and assess the statistical significance of the loss-differential of the unconditional and conditional predictive abilities. As conditional quantiles can be inverted to the conditional distribution, they also test for Granger-causality in the conditional distribution (using a nonparametric copula function). Using U.S. monthly series of real personal income and industrial production for income, and M1 and M2 for money, for 1959 to 2001, they find that out-of-sample quantile forecasting for output growth, particu-
larly in tails, is significantly improved by accounting for money. On the other hand, money-income Granger-causality in the conditional mean is quite weak and unstable. Their results have important implications for monetary policy, showing that the effectiveness of monetary policy has been underestimated by merely testing Granger-causality in mean. Money-income Granger-causality is stronger than it has been known, and therefore the information on money growth can (and should) be more widely utilized in implementing monetary policy.

LOTTERIES

Lotteries are most frequently government-sponsored alternatives to primarily illegal numbers games whereby the participants win cash prizes if they match a series of numbers or symbols. It can be argued that lotteries date back
to biblical times (the process of “casting lots”) and there is considerable historical evidence of lotteries from the sixteenth century forward as a means by which municipalities raised funds for government finance. In the eighteenth and nineteenth centuries numerous lotteries raised very significant revenues to build roads, canals, courthouses, and so on, and in particular, to finance wars (Gribbin and Bean 2006). In the modern era of lotteries (presumed to have begun in 1964 with the initiation of the New Hampshire lottery in the United States), lotteries have generally not generated commensurately large revenues, but have served as an alternative revenue source that is politically expedient due to both participant and nonparticipant perceptions.

Lottery players generally cite the expected utility of a potential win as justification for playing, or at the least, the utility derived from thinking about what they would do with the money if they win. There is limited entertainment value in lottery instruments beyond these measures of expected utility, and no skill. Lottery players also recognize that even if they do not win, their money is designated for a generally desirable beneficiary group such as public schools, the elderly, or specific public works projects. Lottery commissions recognize the lack of entertainment value in their games and thus must constantly innovate to maintain player interest in participation.

Nonplayers appreciate that lotteries allow them to shift a portion of the municipal tax burden to those who do not understand or care about the long odds of winning. Their perception is the opposite of the advertising slogan, that is, “you cannot lose if you do not play.” Legislative leaders understand lotteries for what they have become: tax revenue sources that are not perceived as such, that allow the government representatives to take advantage of fungibility to shift funds to whichever projects or groups they choose, while maintaining the perception of effective earmarking for a desirable recipient group (Borg and Mason 1988).

From a procedural standpoint, lottery games fall into two basic categories: instant games and lottery games. Instant games are mostly scratch-off instruments whereby the player uses a coin or some other means to remove a coating from areas on a card, attempting to match a particular series of like symbols to win a predetermined amount. These games represent a relatively minor portion of the revenue raised by lotteries, but the area in lottery administration that requires the most innovation to maintain player interest. Lotto games are closer to the illegal numbers games mentioned above, requiring the winning player to match from three to six numbers, most frequently printed on ping-pong balls drawn from a container. The payouts in these games are substantial, ranging from hundreds to hundreds of millions of dollars. Most of these lotto games reflect odds that follow simple mathematical combinations, for example \( \binom{53}{6} \) is a standard for many U.S. state games, where \( x \) is 49 numbers, 53 numbers, or some other magnitude. The \( \binom{53}{6} \) game implies that odds of winning are 1 in approximately 22 million. Longer odds are encountered in multistate games that also imply that the last ball drawn reflects a specific number (e.g., the “powerball”).

Lottery games are generally available in a large number of retail locations including grocery stores, convenience stores, and other establishments that are licensed by the municipality to distribute the tickets. Ticket sellers receive a commission for selling the tickets (frequently around 5% of sales) and many also share in the good fortune of winners with extra compensation. Evidence suggests that play increases when ticket availability is found close to either one’s home or workplace. Consequently, lottery ticket sales are frequently higher per capita in large cities as opposed to small towns and rural areas (Clotfelter and Cook 1989).

There are other significant demographic characteristics of lottery players that identify the implications of the tax inherent in lottery games. Consistently, researchers have discovered that lottery players tend to be older, and frequently members of racial and ethnic minority groups. Far more players come from large municipalities. There is significant crossover between states and countries whenever jackpots of the lotto games become large, and women tend to play lottery games slightly more than men. From an economic standpoint, the most significant demographic reality of lotteries is that while lottery play increases with income, it does so at a declining rate, suggesting that the routinely 50 percent tax rate inherent in lottery games is regressive (Clotfelter and Cook 1989, among many).

Among the other economic implications of lotteries, lotteries are inefficient from a tax standpoint. The responsiveness of demand for lotto games to price changes is often greater than one in absolute value, implying that taxes inherent in lottery games do not raise the same levels of revenue for the same cost as other tax sources. This reflects the luxury nature of lottery tickets in the player’s market basket. The magnitude of this effect is mitigated whenever a municipality increases the frequency of lotto games during the week, so current trends have reduced this effect somewhat (Mason, Steagall, and Fabritius 1997). Lottery tax revenues are generally relatively small compared to other tax sources, and are not as stable given that their magnitudes frequently depend on rollovers, and the impact that they have on player frenzy. Earmarking of lottery revenues to specific recipients is a bait-and-switch process that motivates players to justify their involvement while legislative bodies shift funds away from the desig-
nated recipient simultaneously. Numerous studies have shown that designated recipients of lottery revenues, for example, public education, are often worse off after the creation of a lottery (see, for example, Gribbin and Bean 2006). As more states adopt lotteries, the competition for lottery player dollars becomes more intense while the attractiveness of playing lottery games wane. This makes it likely that future lottery revenues generated by all states will diminish.

In summary, lotteries are a means by which legislative groups motivate individuals to provide tax revenue that they do not perceive as such in exchange for minute chances of winning cash awards. The economic consequences of these lotteries are just as condemning. Perhaps the best perspective on lotteries is that “your odds of winning are almost as good if you do not play.” The forty-one states in the United States and many municipalities around the world should learn this lesson to generate more stable and more conscientious government revenue generation.

LOVE CANAL

In 1894 entrepreneur William T. Love began building a canal to connect the Niagara River to Lake Ontario. The canal was to provide water and hydroelectric power for the city of Niagara Falls, New York. Some eighty-four years later, however, the canal became a symbol of the threat of toxic chemical wastes to human communities and the environment, and Love Canal became a moniker for a social movement whose advocates believe that all people are entitled to protection from such hazards.

Love sold his partially completed sixteen-acre canal at public auction in 1947. There was a nationwide depression that had left him short of funds, and the invention of alternating electrical current had rendered his hydroelectric project obsolete. Hooker Chemicals and Plastic Corporation (later known as Hooker Chemical Corporation, and more recently as Occidental Chemical Corporation or OxyChem) bought the site after determining it was isolated and sparsely populated at the time and had an impermeable clay substrate, which made it a good location for a chemical waste landfill. According to New York state officials, the city of Niagara Falls and some federal agencies (including the military) regularly dumped chemical and other wastes at the site, in addition to the approximately 21,800 tons of chemical wastes dumped by Hooker until 1952. The company sold the site for one dollar in 1953 to the Niagara Falls Board of Education, which intended to eventually construct a grade school and playground on it.

Subsequent events ignited controversy over who—Hooker or the Niagara Falls Board of Education—was legally responsible for the exposure of the public to the chemical wastes and the resulting illnesses experienced by families who resided in the area. Despite the restrictions and risk stipulations in the deed conveyed to the Board of Education by Hooker, the Board decided to develop the land above the fill site and its surrounding area. The Board authorized construction of an elementary school on the site in 1955, the city constructed a sewer line through the canal in 1960, and developers constructed homes and streets next to the site. The toxic chemicals stored there eventually seeped from their ruptured and deteriorated containers into the soil, basements, and storm sewers. In April 1978, Michael Brown, a reporter for the Niagara Gazette, wrote a series of articles on hazardous wastes in the Niagara Falls area. By August 1978, the New York health commissioner declared a state of emergency in the area, and 239 families were evacuated. Five days later President Jimmy Carter approved emergency financial aid to permanently relocate these families. In March 1980 the president declared a state of emergency at Love Canal and funded the permanent evacuation and relocation of an additional 780 families. Brown drew national attention to the disaster in his 1980 book Laying Waste: The Poisoning of America by Toxic Chemicals.

State and federal investigations into the conditions at the landfill identified 248 different chemicals and 82 chemical compounds, 11 of which were known carcinogens. These toxins included benzene, toluene, chloroform, carbon tetrachloride, lindane, and trichlorophenol that
was contaminated with the carcinogen dioxin. Residents exposed to these and other chemicals reported miscarriages, birth defects, cancer, and asthmatic, urinary, and convulsive disorders. Beginning in 1979, residents initiated a series of lawsuits against Hooker, the city, the Board of Education, and several public agencies. In April 1980 the State of New York filed a $635 million lawsuit against Occidental Petroleum (OxyChem’s parent company) and its two subsidiaries, charging that the companies were responsible for the Love Canal disaster. The New York Supreme Court announced three years later a $20 million settlement of the 1,337 claims filed. Occidental Petroleum agreed in 1989 and later paid the Environmental Protection Agency $129 million for cleanup costs.

Epidemiological evidence of chemical exposure causing abnormal rates of acute and chronic illness has been controversial. Studies conducted by scientists and by the New York State Department of Health as recently as 1997 found that the residents who lived closest to the canal experienced rates of certain diseases (for example, liver disorders and lymphomas, leukemia, and several other cancers) that were no different from those of control groups who lived elsewhere in the county and in upstate New York. Other findings showed, however, that Love Canal residents had higher rates of spontaneous abortions, childhood disorders, lung and respiratory disorders, and female genitourinary cancers.

In 1988, based on its own five-year study and further investigation by the Environmental Protection Agency, the New York State Department of Health concluded that a segment of the canal area was again habitable and proposed to resettle the area. Lois Gibbs, who had organized the Love Canal Homeowners Association in 1978 and whose son had attended the contaminated elementary school, energized the public to fight against the state’s effort to move families back to the canal area. In 1981 Gibbs founded the Citizens’ Clearinghouse for Hazardous Wastes (later renamed as the Center for Health, Environment, and Justice).

The Citizens’ Clearinghouse became a national resource that provided guidance and education to many of the grassroots groups and people of color who opposed chemical wastes and emissions in their communities and neighborhoods. These groups and their supporters helped define the early agenda of the American environmental justice movement, and they drew media and political attention to socioeconomic inequities (e.g., environmental racism) associated with waste facility siting, industrial emissions, and regulatory enforcement. Their collective efforts galvanized public awareness of these issues during the 1980s and 1990s and bridged other major social movements involving civil rights, feminism, and worker safety.

LOWE, ADOLPH

SEE Economics of Control.
LOWI, THEODORE J.
1931–

Theodore J. Lowi is known within the fields of political science, sociology, and law for his statement of interest-group liberalism, a theory of political power in the United States widely accepted (particularly in the 1970s and 1980s) as an alternative to the pluralist theory of political power advocated by Robert A. Dahl (b. 1915). In The End of Liberalism (1979) Lowi presumed that single-power-elite theories of U.S. politics are generally incorrect, in that Lowi described political power as wielded by different elites in different policy areas. But his interpretation of this research finding was very different from the pluralist interpretation. Lowi argued that such fragmented power leads to the control of most domestic policy areas by special-interest coalitions of interest groups, administrators, and legislative committee members, who are unresponsive to control by legislative and executive leaders, or by the judiciary. Lowi’s use of the term liberalism in this theory does not refer to the political opinions of some Americans, but to the term’s use in political philosophy, referring to those defining democracy according to some process of decision making, rather than to those referring to standards of justice in the substance of government action. Lowi argued that liberalism in the process sense had come to permeate the values of legislative, executive, and judicial decision makers in the United States, so that laws were written and interpreted without useful reference to clear standards of justice and administration. He argued that as a consequence, lower-level executive decision makers interpreted the practical meaning of legislation after a process of bargaining with organized interest groups, thereby forming a special-interest policymaking coalition specific to a particular area of public policy. To reform interest-group liberalism, Lowi advocated institutional changes to promote the statement of clear standards in legislation and administration of public policy, such as judicial prohibition of legislation lacking such clear standards.

In 1976 a survey of political scientists ranked Lowi as having “made the most significant contribution to the discipline” from 1970 to 1976 (Roettger 1978). During the 1970s Lowi’s interpretation of power and policymaking was not effectively challenged by other scholars. The power-elite theory of C. Wright Mills had been discredited within political science by the criticisms of the pluralists, led by Robert A. Dahl (Mills 1956; Dahl 1961), although political scientists often apply a version of elite theory to foreign policy decisions. The more complex elitist theory of Thomas R. Dye (ranked third in the above survey) and L. Harmon Zeigler simply included Lowi’s policy-area elites as a part of their description of a national policymaking elite numbering in the thousands (1975, pp. 274–276, 394). Faced with about twenty case studies of particular national policy areas tending to support Lowi’s theory, the pluralists did not attempt a general criticism of Lowi’s views. Instead, they directed their research at dealing with the question of control of the political agenda (Polsby 1980). Lacking much in the way of opposing argument, Lowi’s views about power and policymaking were preeminent for about a decade. However, research by a later generation of pluralists found that many areas of domestic policymaking actually show numerous interest groups in contention with one another, thereby precluding domination of a policy area by a single coalition (Walker 1991). These neopluralist critics agreed that the pattern described by Lowi can be found in some areas, known as “policy niches.”

The End of Liberalism is based on Lowi’s previous delineation of three types of public policies: distributive, regulatory, and redistributive. (Lowi added a fourth, government reform, somewhat later.) Distributive policies encompass the distribution of particular benefits, usually material ones such as government contracts, grants, and construction projects. As interest groups cooperate to divide up such goods, distributive policies tend to exhibit little conflict and are characterized by interest-group liberalism. Regulatory policies regard the passage and enforcement of legal regulations such as labor law, civil rights law, environmental rules, and so forth. Such policy areas often show the politics of pluralist conflict among interest groups, unless the regulations set unenforceable standards, in which case interest-group liberalism prevails. Redistributive policies take wealth from the rich and give to the poor, and are characterized by class politics, uncommon in the United States. Lowi’s contrasts among these three types of policies are now widely accepted by political scientists.

LOWIE, ROBERT
1883–1957

Robert Harry Lowie, an Austrian-American anthropologist, was one of the leaders of Franz Boas’s (1858–1942) first generation of students. Lowie was noted for his contributions to American Indian ethnography, social structure, and ethnological theory.

Born to a middle-class Jewish family in Vienna, Austria, Robert Lowie was the son of Samuel Lowie, a Hungarian-born businessman, and Ernestine Kuhn Lowie, the daughter of a Viennese physician. Immigrating with his family at the age of ten, he attended public school in New York City. In 1901 Lowie graduated with a BA in classics from the City College of New York. After teaching briefly in the New York school system, he enrolled in Columbia University, where he was soon attracted to anthropologist Franz Boas and his embodiment of German scientific ideals. Entering the doctoral program in anthropology in 1904, Lowie earned his PhD in 1908 with a dissertation on “The Test-Theme in North American Mythology.”

Robert Lowie joined curator Clark Wissler (1870–1947) at the American Museum of Natural History, which sponsored Lowie’s first field work in 1906 among the Lemhi (Northern Shoshone) of Idaho. The following year, Lowie officially joined the staff of the museum as an assistant, becoming assistant curator in 1909 and associate curator in 1913. During his tenure at the museum, Lowie carried out most of his ethnographic fieldwork, studying the Assiniboine, Northern Blackfoot, Chipewyan, Hidatsa, Southern Ute, Southern Paiute, Northern Paiute (Paviotso), Washo, and Hopi. Despite this wide range, Lowie’s specialty was the Native peoples of the Great Plains, particularly the Crow of Montana. He first worked among them in 1907, returning every summer from 1910 to 1916, and again in 1931.

In most respects, Lowie’s ethnography was thoroughly Boasian. Motivated by the “salvage paradigm,” predicated on the disappearance of Native cultures, in his ethnography he focused on a general cultural survey that called for the mapping of cultures and languages. His fieldwork was also holistic and comprehensive, studying every aspect of a group’s culture from artifacts to social organization to religion and mythology.

After spending a year teaching anthropology at the University of California, Berkeley (1917–1918), Lowie joined the faculty as an associate professor in 1921, becoming a full professor in 1925 and retiring in 1950. During the 1930s, Lowie developed a new areal interest: South America. He edited and translated the writings of Curt Nimuendajú (1883–1945), a German-Brazilian ethnographer of the Ge-speaking peoples of Brazil. These interests led to his planning and support for the Handbook of South American Indians (1946–1959), edited by his student Julian Steward (1902–1972).

Many of Lowie’s books stemmed from his interest in summarizing the state of anthropological knowledge and communicating it to a broadly educated general audience; these included Culture and Ethnology (1917), Primitive Society (1920), Primitive Religion (1924), and Social Organization (1948). His interest in cultural critique, expressed in Are We Civilized? (1929) and other essays of the 1920s, led to his Toward Understanding Germany (1954), a detailed anthropological analysis of a European society.

In anthropological theory, Robert Lowie was known for his empiricism, inspired by youthful influences of Ernst Mach (1838–1916) and Ernst Haeckel (1834–1919). Lowie thought it important to emphasize facts and distinguish them from interpretation, amassing full and accurate evidence with an aversion to premature generalization. At the center of his interests was social organization, both in kinship and in voluntary associations such as Plains Indian military societies. Primitive Society, his major work on the subject, embodied the Boasian critique of Lewis Henry Morgan’s (1818–1881) unilinear evolution. Lowie’s famed characterization of culture as “a thing of shreds and patches” expressed the Boasian belief that while the sources of any given culture might be diverse, they were integrated in a unique pattern. Lowie extended this approach in his formulation of the method of controlled comparison. His interest in the philosophy of science revealed itself in his History of Ethnological Theory (1937), one of the first summaries of its kind. Like all his work, it was distinguished for its grasp of international scholarship.

In 1933, at the age of fifty, Lowie married Luella Cole (1893–1970), a psychologist; they had no children. In the course of his long career, Lowie received many professional honors, including service as the editor of American Anthropologist (1924–1933) and president of the American Folklore Society (1916–1917), American Ethnological Society (1920–1921), and American Anthropological Association (1935–1936). A socialist in his youth, he was a pacifist during World War I (1914–1918) and a passionate opponent of Nazism. Robert Lowie died of cancer in Berkeley; his papers are preserved.

LOW-INCOME LIFESTYLES

descendants of the American loyalists, but of subsequent waves of American economic migrants and British immigrants (Kaufmann 1997).

At the time of Canadian confederation in 1867, roughly half the English-speaking population of Canada was of Scottish or Irish-Protestant extraction. The large-scale movement of Irish-Protestant settlers to Canada brought the other major “loyalist” ethnic group together with its Canadian soul mate. Protestants in Ireland were mainly the descendants of English and Scottish settlers from the early 1600s. The Anglo-Irish elite derived from a longstanding high-church Anglican population whose cultural life was centered upon Dublin. However, the bulk of the Protestant population was “planted” by the British Crown from Elizabethan times (post–1600), mainly in the nine northern counties comprising Ulster.

Irish loyalism was initially divided because Presbyterians and other dissenting sects experienced discrimination (such as the nonrecognition of marriages) from the Anglican authorities. Fired by Whig ideas, Presbyterians were in the forefront of both the American Revolution (1775–1783) and the uprising of the United Irishmen in Ireland in 1798. Both movements sought independence from Britain and were inspired by liberalism rather than anti-Catholicism. However, popular conflict at the everyday level between Protestants and Catholics was a reality upon which political entrepreneurs could draw. After all, there was a history of sectarian strife and bloodshed, especially around the English Civil War in the 1640s. As the United Irishmen began to seek support from the Catholic Defender movement, with its Catholic-rights agenda, a countermovement sprang up among the Protestants. This movement coalesced into the Loyal Orange Order, formed in 1795 near Portadown in County Armagh after a series of local sectarian skirmishes. Based on the structures of freemasonry, Orangeism rapidly spread throughout Ireland, where it espoused an ideology of loyalty to Protestantism and to the Crown, which served as the political defender of Protestantism in the British Empire (Haddick-Flynn 1999).

Orangeism was soon exported to Scotland and England (by 1810) and Canada (by 1820) with returning British soldiers and through Irish-Protestant emigration. In Canada, it was so successful that it surpassed the Irish organization in numbers soon after 1900. The late nineteenth century saw the emergence of a full-blown Britnic nationalism, an expression of pride in British ethnic origins and political achievements that spanned Britain, Ireland, Canada, Australasia, and South Africa (Cole 1970). This imperial sentiment colored loyalism in Canada and Ireland. But it never displaced the metropole-settler dualism that is the hallmark of loyalist identity.

The decline of the British Empire drove home the local (or settler) side of loyalist identity for Canadians (as well as Australians, Scots, and Newfoundlanders), leading to new expressions of local nationalism in these places. In Canada, loyalty died hard, as witnessed in the 1965 debate over whether to retain the Union Jack or adopt a new maple leaf flag (Buckner 2004). In Ireland, the home rule crisis of 1884 to 1886 proved the last time that the Irish Protestants could count on Unionist support from mainland Britain. After the second home rule crisis of 1912 to 1914, Irish Protestants began to militarily organize and mentally prepare themselves to go it alone in the six Protestant-majority counties in the northeast of Ulster. The Northern Ireland Act of 1922 recognized the Protestant-dominated Northern Ireland state, restoring the British loyalty of the Ulster-Protestants. However, this loyalism was tested again in the 1960s when agitation by the 35-percent Catholic minority led the British government to press loyalists to reform their system of local government and housing, and share power with Catholics. When such reforms were not forthcoming, the British stepped in to directly rule the province, but by then the Irish Republican Army (IRA) military and terror campaign was in full swing. Twenty-five years of bombing and violence ensued, as the British army and its loyalist auxiliaries (local police and defense regiments) tried to subdue the IRA.

With the IRA ceasefires in 1995 and 1997, and the Good Friday Agreement of 1998, some saw a new dawn for Northern Ireland. Catholics made gains toward economic and political parity with Protestants, but power sharing, premised on the inclusion of Sinn Fein/IRA in government, proved a nonstarter for most Protestants. By 2007, decommissioning of IRA weapons remained the main obstacle to peace, but changes within loyalism were also important. Loyalists have increasingly turned inward, shifting from being “loyal” to “rebels” Unionists (Kaufmann 2007). Skeptical of Britain for “selling us out,” they have begun to celebrate their Scottish roots, their Ulster-Scots dialect, and their role in anti-British episodes like the American Revolution and even the United Irish uprising. Though most identify as “British,” this label does not connote civic attachments to the British state, but rather an ethnic attachment to the Ulster-Protestants and their six-county homeland of “Ulster.”

LUCAS, ROBERT E., JR.
1937–

Born September 15, 1937, in Yakima, Washington, Robert E. Lucas Jr. was the first child of the owners of the Lucas Ice Creamery, which did not survive the 1937–1938 downturn. After completing his BA in history at the University of Chicago in 1959, he enrolled in graduate school at the University of California at Berkeley, where he became interested in economic history and decided he needed more background in economics. This brought him back to the University of Chicago, where he became so interested in economics that he obtained his PhD in this field in 1964. Lucas worked at Carnegie Mellon University, originally known as the Carnegie Institute of Technology, until 1974, when he returned once again to the University of Chicago. In 1995 Lucas received the Nobel Memorial Prize in Economics “for having developed and applied the hypothesis of rational expectations, and thereby having transformed macroeconomic analysis and deepened our understanding of economic policy.” Indeed he is often considered the preeminent macroeconomist of the last quarter of the twentieth century.

Lucas is one of the founding fathers of new classical macroeconomics, which contrasts sharply with the Keynesian insights that dominated macroeconomics through the 1960s. The new classical paradigm starts from the premise that economics has to account for the decisions made by firms and people in ways that are consistent with the idea of optimizing behavior, because ad hoc assumptions about their behavior are not compatible with the microfoundations of economic theory. At the same time Lucas criticized the typical Keynesian assumptions that markets do not clear and that economic agents do not always pursue optimizing strategies. In addition he challenged adaptive expectations economists for working with models that forecast better than agents, thereby leaving space for the non-neutrality of money in the short run. These insights are associated with, among others, Milton Friedman and Anna Schwartz. Instead, Lucas obliterated the distinction between the short run and the long run. Overall then Lucas may be viewed as replacing earlier ad hoc treatments with an approach squarely based on the microfoundations of incentives, information, and optimization.

Lucas has made contributions to a wide variety of fields, including financial economics, monetary theory, public finance, international economics, and economic growth. In the last he contributed the insights that human capital accumulation has significant external effects and that learning by doing plays an important role in the process of human capital accumulation. He is known especially for the so-called Lucas critique, according to which parameters of economic relationships are likely to change due to policy changes, rendering them unreliable for making policy recommendations. By overturning the basis for governmental fine-tuning, this transformed thinking on economic policy and inspired Lucas to develop powerful and operational methods for drawing conclusions from models that avoid this pitfall. In particular he is known for his efforts to embed theories in general equilibrium dynamics.

The attempts of Lucas and his colleagues to create microfoundations for macroeconomics ran into a major stumbling block in the shape of the Sonnenschein-Debreu-Mantel results, which established that the standard microeconomic model has almost no implications for macrobehavior. In response macroeconomists have turned to representative agent analysis (Kirman 1992) and endeavored to incorporate some kind of bounded rationality (Sargent 1993; Sent 1997). In some sense, this is moving them away from Lucas’s original insights.

**LUCKAS CRITIQUE**

In an extremely influential 1976 article, American economist Robert E. Lucas Jr. questioned the ability of econometric models to predict the effect of policy experiments. According to Lucas, reduced-form econometric models are not able to provide useful information about the outcomes of alternative policies because the structure of the economy changes when policy changes.

Lucas describes the economy in time, $t$, by a vector $y_t$ of state variables, a vector $x_t$ of exogenous forcing variables, and a vector $e_t$ of independent and identically distributed random shocks. One estimates the values of a fixed parameter vector $\theta$, with the $F$ function of behavioral relationships suggested by economic theory:

$$y_{t+1} = F(y_t, x_t, \theta, e)$$  \(1\)

With knowledge of $F$ and $\theta$, policy evaluation becomes straightforward. However, $F$ and $\theta$ derive from (optimal) decision rules of the economy. It is the central assumption that once $F$ and $\theta$ are approximately known, they will remain stable under arbitrary changes in the behavior of $x_t$. To assume stability of $(F, \theta)$ under alternative policy rules is to assume that agents' views about the behavior of shocks to the system are invariant under changes in the true behavior of these shocks. The empirical implication is that the estimated vector $\theta$ is not invariant but will change with policy interventions, which invalidates forecasts and policy predictions. Under (1), Lucas (1976) discusses in turn the aggregate consumption function, the investment function (reconsidered in Oliner et al. 1996), and the popular Phillips curves of the 1970s.

The reaction to the Lucas critique has been to formulate dynamic macromodels with rational expectations and optimizing foundations. Empirical evidence has suggested that price and real variables exhibit gradual responses to shocks. Given that forward-looking specifications with those desirable foundations do not replicate features from the data, reconsiderations have followed, such as Arturo Estrella and Jeffrey Fuhrer (2002) in macromodels and George Evans and Garey Ramey (2006) under adaptive expectations.

Other studies have delved into the framework in (1). Jesper Lindé (2001) examines money demand (MD) and consumption functions (CF) to see whether the $\theta$-parameters are dependent on the monetary policy Taylor-rule (TR). There are two sets of observations $[1, 2, ..., T/2; (T/2) + 1, ..., T]$ under the assumption that TR changes unexpectedly after $T/2$ periods from one monetary policy regime to another. See also Richard Clarida et al. (2000) on shifting monetary policies at the U.S. Federal Reserve.

Estimating parameter vectors for all functions in both subperiods ($\theta_1^1$ and $\theta_2^1$), Lindé employs breakpoint tests to see whether the null hypothesis of equal parameters is rejected and concludes that the Lucas critique is quantitatively important in a statistical sense. It remains to be seen whether changes in the $\theta$-parameters are sufficiently large to cast doubt on forecasting exercises. The methodology then tests, according to the Lucas critique, whether the null $(H_0: \theta_{MD}^1 = \theta_{MD}^2, \theta_{TR}^1 = \theta_{TR}^2)$ is false. If the computed probabilities of rejecting parameter stability in MD and TR at the same time are low, the power of the test (defined as $1 - \beta$, where $\beta$ is the type-II error or the probability of not rejecting $H_0$ given that $H_0$ is false) is low in small samples. Simulations in Lindé suggest this is indeed the case, although the tests are given the best possible environment for detecting regime shifts. This implies that the methodology used is not capable of detecting the relevance of the Lucas critique in small samples. This negative finding suggests further work along these lines seems warranted.

LUCK

Luck exerts a dramatic influence over people’s lives. It has the power to transform the improbable into the possible; to make the difference between life and death, reward and ruin, happiness and despair. But how do psychologists examine this elusive concept, and what has this work revealed?

Some researchers have examined why some people are consistently lucky while others encounter little but ill fortune. This work has employed a variety of methods, including interviews, diary studies, personality questionnaires, and laboratory-based research. The findings suggest that luck is not a magical ability or the result of random chance. Instead, although lucky and unlucky people have almost no insight into the real causes of their good and bad luck, their thoughts and behavior are responsible for much of their fortune. Lucky people tend to be skilled at creating and noticing chance opportunities, create self-fulfilling prophesies via positive expectations, and adopt a resilient attitude that transforms bad luck into good.

Take, for example, the notion of “lucky breaks.” Lucky people consistently report encountering such opportunities whereas unlucky people do not. Researchers have conducted several experiments to discover whether this is due to differences in their ability to spot such opportunities. One such experiment involved giving both lucky and unlucky people a newspaper, asking them to look through it, and asking them to state how many photographs were inside. Participants were unaware that a large opportunity had been placed in the newspaper, in the form of an advertisement announcing: “Tell the Experimenter You Have Seen This and Win $250.” The message took up half of the page and was written in type that was over 2 inches high. However, the unlucky people tended to miss the ad and the lucky people tended to spot it. Why was this the case?

Personality tests suggest that unlucky people are generally much more tense and anxious than lucky people, and research has shown that anxiety disrupts people’s ability to notice the unexpected. In one experiment, people were asked to watch a moving dot in the center of a computer screen. Without warning, large dots would occasionally be flashed at the edges of the screen. Nearly all participants noticed these large dots. The experiment was then repeated with a second group of people, who were offered a large financial reward for accurately watching the center dot. This time, people were far more anxious during the experiment. They became very focused on the center dot and over one-third of them missed the large dots when they appeared on the screen. The harder they looked, the less they saw. And so it is with luck: unlucky people miss chance opportunities because they are too focused on looking for something else; lucky people are more relaxed and open, and therefore see what is there rather than just what they are looking for.

Another important aspect of the psychology of luck revolves around the way in which lucky and unlucky people deal with the ill fortune in their lives. Imagine an individual is chosen to represent his or her country in the Olympic Games. The participant competes in the games, does very well, and wins a bronze medal. How happy would the person feel? Most people would probably be overjoyed and proud of their achievement. Now imagine instead that the individual competes at the same Olympic Games a second time. This time he or she does even better, and wins a silver medal. How happy would the person feel now? Most people think that one would feel happier after winning the silver medal. This is not surprising. After all, the medals are a reflection of one's performance, and the silver medal indicates a better performance than a bronze medal. But research suggests that athletes who win bronze models are actually happier than those who win silver medals. And the reason for this has to do with the way in which the athletes think about their performance. The silver medalists focus on the notion that if they had performed slightly better, then they would have perhaps won a gold medal. In contrast, the bronze medalists focus on the thought that if they had performed slightly worse, then they would not have won anything at all. Psychologists refer to one's ability to imagine what might have happened, rather than what actually did happen, as counterfactual thinking.

Lucky people use a certain type of counterfactual thinking to soften the emotional impact of the ill fortune that they experience in their lives. In one study, lucky and unlucky people were presented with some imaginary scenarios and asked how they would react. For example, one such scenario involved the following:

Imagine that you are waiting to be served in a bank. Suddenly, an armed robber enters the bank, fires a shot and the bullet hits you in the arm. Would this event be lucky or unlucky?
Unlucky people tended to say that this would be enormously unlucky and it would be just their bad luck to be in the bank during the robbery. In contrast, lucky people viewed the scenario as being far luckier, and often spontaneously commented on how the situation could have been much worse. Lucky people tend to imagine spontaneously how the bad luck they encounter could have been worse and, in doing so, they feel much better about themselves and their lives. This, in turn, helps keep their expectations about the future high, and, increases the likelihood of them continuing to live a lucky life.

People have searched for an effective way of improving the good fortune in their lives for many centuries. Lucky charms, amulets, and talismans have been found in virtually all civilizations throughout recorded history. Such beliefs represent people's attempts to control and enhance their luck. Research suggests the time has come for them to put their lucky charms away, and start to change the way they think and behave.

LUDDITES

Few groups have been more misunderstood and have had their image and name more frequently misappropriated and distorted than the Luddites. The term Luddite has typically referred to an individual who is opposed to technological change, and is derived from various tales in the Midlands stocking trade about an apprentice named Ned or Edward Ludd who broke his frame or needles in response to his master's strict discipline. (No actual person named Ned Ludd has been identified.) The Luddites were not, as popularizers of theories of technology and capitalist apologists for unregulated innovation claim, universally technophobes. They were artisans—primarily skilled workers in the early-nineteenth-century English textile industry. When faced with attempts to drive down their wages through the use of machines (operated at lower wages by less-skilled labor) the Luddites turned to wrecking the offensive machines and terrorizing the offending owners in order to preserve their wages, their jobs, and their trades. These men objected not only to the threat to their wages, but also to the production of cheap, inferior goods, which they feared would damage the reputation of their trades. Machines were not the only, or even the major, threat to the textile workers of the Midlands and North, however. The Prince Regent's Orders in Council, barring trade with Napoleonic France and nations friendly to France, cut off foreign markets for the British textile industry. Even more importantly, high food prices required more of each laborer's shrinking wages. Machines and those masters who used them to drive down wages were simply the most accessible targets for expressions of anger and direct action.

LUDDITE DEMOGRAPHICS

The Luddites varied by region and profession. In the Midlands counties of Nottinghamshire, Leicestershire, and Derbyshire, the Luddites comprised (almost exclusively) workers in the framework-knitting and lace trades. Midlands Luddism began in 1811 and ended in 1817 with the executions of men convicted for their roles in the 1816 attack on John Heathcoat's Loughborough mill. Yorkshire Luddism centered on the woolen trade. Most Yorkshire Luddites were croppers (highly skilled artisans who cropped the nap off of woven woolen cloth to smooth it), but the croppers found support among other skilled workers, such as saddle-makers. Yorkshire Luddism began in early 1812 and ended with the executions of several convicted Luddites in York in 1813. Luddism in the Cotton Districts surrounding Manchester encompassed not only trade-based protest but also political agitation. Luddites there were made up largely of cotton weavers, supported at times by colliers and by women in no-trade at all, but spinners also played an important role in Luddite riots in Manchester and Flintshire. In Manchester, north Cheshire, and north Derbyshire, Luddism was frequently joined to food rioting and agitation for political reform.

PRIOR HISTORY OF MACHINE-BREAKING

The Luddites were neither the first nor only machine wreckers. Because organized, large-scale strikes were impractical due to the scattering of factories throughout
different regions, machine-wrecking, which E. J.
Hobsbawm calls “collective bargaining by riot,” had
occurred in Britain since the Restoration. For example, in
1675 narrow weavers in the area of Spitalfields destroyed
“engines,” power machines that could each do the work of
several people, and in 1710 a London hosier employing
too many apprentices in violation of the Framework
Knitters Charter had his machines broken by angry
framework knitters, also called stockingers. Even para-
nlementary action in 1727, making the destruction of
machines a capital felony, did little to stop the activity. In
1768 London sawyers attacked a mechanized sawmill.
Following the failure in 1778 of the stockingers’ petitions
to Parliament to enact a law regulating “the Art and
Mystery of Framework Knitting,” Nottingham workers
rioted, flinging machines into the streets. In 1792
Manchester weavers destroyed two-dozen Cartwright
steam looms owned by George Grimshaw. Sporadic
attacks on machines (wide knitting frames, gig mills,
shearing frames, and steam-powered looms and spinning
jennies) continued, especially from 1799 to 1802 and
through the period of economic distress after 1808.

THE COURSE OF LUDDISM
The first incident during the years of the most intense
Luddite activity, 1811 to 1813, was the March 11, 1811,
attack upon wide knitting frames in a shop in the
Nottinghamshire village of Arnold, following a peaceful
gathering of framework knitters near the Exchange Hall in
Nottingham. In the preceding month, framework knitters
had broken into shops and removed jack wires from wide
knitting frames, rendering them useless without inflicting
great violence upon the owners or incurring risk to the
stockingers themselves; the March 11 attack was the first
in which frames were actually smashed and the name
“Ludd” was used. The grievances consisted, first, of the
use of wide stocking frames to produce large amounts of
cheap, shoddy stocking material, and, second, of the
employment of “colts,” workers who had not completed
the seven-year apprenticeship required by law. Employers’
violations not only of the law against hiring “colts,” but of
a number of other laws as well—such as the prohibition
against the use of the gig mill and the limitation on the
number of looms any weaver could possess—provided
Luddites with justification for direct action against the
employers. In probably the best example of such valida-
tion, the framework knitters, who launched the Luddite
protests in Nottingham in 1811, justified their actions by
referring to their own originary or constitutive charter, the
1663 Charter of the Company of Framework Knitters.

Frames continued to be broken in many of the vil-
lages surrounding Nottingham. The March 23, 1811, and
April 20, 1811, Nottingham Journal reported several weeks

of almost nightly attacks in the villages, all successful and
carried out with no arrests. The summer of 1811 was
quiet, but a bad harvest helped to renew disturbances in
November, when, as the story goes, stockingers assembled
in the wooded lands near Bulwell and were led in attacks
on a number of shops by a commander calling himself
Ned Ludd.

Midlands authorities’ letters dated November 13 and
14, 1811, request that the government dispatch military
aid because “2,000 men, many of them armed, were
riotously traversing the County of Nottingham.” In
December 1811 public negotiations between the frame-
work knitters and their employers, the hosiers, failed to
result in the return of wages, piece rates, and frame rents
to earlier levels or in any satisfactory improvement of the
framework knitters’ economic circumstances. Frame-
breaking continued in Nottinghamshire, Derbyshire, and
Leicestershire through the winter and early spring of
1812. It resurfaced in 1814 and again in Leicestershire in
the autumn of 1816.

The first signs of the spread of Luddism to the cot-
ton-manufacturing center of Manchester and its environs
in Lancashire, Cheshire, and Flintshire materialized in
December 1811 and January 1812. Manchester Luddism
centered on the cotton-weaving trade, which was suffering
from the use of steam-powered looms, but Luddites there
were active in defense of the spinning trade as well. In
Manchester, unlike Nottingham, large factories housed
the offensive machinery. Large numbers of attackers
tended to carry out the Luddite raids in and around
Manchester; these also often coincided with food riots,
which provided crowds that were large enough to carry
out the factory attacks. Luddite activity continued in
Lancashire and Cheshire into the summer of 1812 and
blended into efforts to establish larger trade combinations
and into political reform, but the force of Luddism dissi-
pated following the acquittal of dozens of accused
Luddites in Lancaster later that year.

The factory owners and cloth merchants of the
woolen industry in the West Riding of Yorkshire were the
targets of Luddism in that county. Although West Riding
Luddites represented a variety of skilled trades, the most
active and numerous by far were the cloth dressers, called
croppers, whose work was threatened by the introduction
of the shearing frame. The croppers’ work consisted of
using forty- or fifty-pound handheld shears to cut, or
crop, the nap from woven woolen cloth in order to make
a smooth and salable article. They were threatened by two
types of machines. The gig mill, which had been prohib-
ited by law since the rule of Edward VI, was a machine
that raised the nap on woolen cloth so that it might be
sheared more easily. The shearing frames actually mecha-
nized the process of shearing and reduced the level of skill
and experience necessary to finish an article of woolen cloth, even though the machines could not attain the quality of hand-cropped cloth. From January 1812 through midspring, Luddite attacks in Yorkshire concentrated on small cropping shops as well as large mills where frames were used. In April, Luddites began to attack mill owners and raided houses and buildings for arms and lead. Luddism began to lose steam after the failed attack upon Rawfolds Mill and the murder of mill owner William Horsfall by George Mellor and other Luddites. By the next winter, West Riding Luddism had run its course, even though after the January 1813 executions of Mellor and other Luddites a few more threatening letters were sent to public officials.

In all three regions, Luddites responded to the distressing concurrence of high food prices, depressed trade caused by the wars and by the trade prohibitions imposed under the Orders in Council, and changes in the use of machinery so as to reduce wages for the amount of work done. That machinery alone was not the primary cause of Luddite anger is evident in the cessation of Luddism. Luddite activities ended following the rescinding of the Orders in Council, some wage and usage concessions, and some reduction in food prices. While Malcolm Thomis (1970) has argued that Luddism was not a concerted agitation for political reform, but simply a common label applied to a range of unconnected protestors in different trades in different regions, it is perhaps more accurate that there were several Luddisms (see Randall 1991; Binfield 2004). Despite its brief run, Luddism ought to be understood, as J. L. Hammond and Barbara Hammond (1919) and E. P. Thompson (1963) have argued, as an important step in the formation of a class-consciousness and in the development of labor unions in Britain.

**LUKACS, GEORG**

*1885–1971*

Georg Lukacs was a Hungarian Marxist philosopher who was profoundly influential on leftist social thought and whose reputation has fluctuated in light of a long life of controversy and productivity. Like his early friend and contemporary, Karl Mannheim, Lukacs was originally trained in Neo-Kantian philosophy, especially Georg Simmel’s formalist aesthetics. The theme of form overcoming matter through collective action, prominent in this period as an account of artistic schools, became a hallmark of Lukacs’s generally realist aesthetic sensibility as well as his approach to revolutionary politics.

The turning point in Lukacs’s life came in 1917 with the onset of the Bolshevik Revolution. As Lukacs himself put it, he became eager to play St. Augustine to Lenin’s Jesus. He thus spent the rest of his life systematizing and justifying Communist ideology, including service as a high-ranking party official in both Moscow and Budapest. While often the dutiful apparatchik, Lukacs sometimes dissented and distanced himself from Leninist and Stalinist policies, more so after Stalin’s death, albeit through the communist practice of “self-criticism.” Here Lukacs may be compared with Martin Heidegger, who originally saw Hitler as his standard-bearer but then withdrew from Nazi politics once his own ambitions were thwarted—though never with a formal renunciation.

To his defenders, Lukacs’s most enduring legacy is a scholarly recovery of the Hegelian roots of Marxism, otherwise known as “Marxist humanism.” Instead of reading...
Marx as a strict economic determinist or scientific materialist, as a focus on *Capital* might suggest, Lukacs stressed Marx’s original training in dialectics as applied to the law. On this basis, Lukacs popularized the term “alienation” to express what he called the “reification” of social relations, whereby people come to be defined in terms of properties that are subject to exchange relations. Following Marx, the key human property for Lukacs is labor, which he understood more as an open-ended and dynamic “praxis” than a mathematical constant in a production function.

This rather existentialist conception of the Marxist project influenced the Frankfurt School’s emphasis on culture in the 1920s and was revived as a distinctly post-Stalinist “Western Marxism” in the 1960s, which continues to underwrite most academic Marxist theory, especially in the humanities. However, Lukacs used his revisionist reading of Marx to idealize Lenin’s practice of organizing a vanguard of intellectuals to consolidate class consciousness in the workers, rendering them a “proletariat” possessed of what Lukacs called the “objective possibility” of revolutionizing society.

The continuing allure of Lukacs’s version of Marxism lies in its thoroughly formal characterization of the conditions for revolutionary politics, one that does not presuppose the success of any historic revolutions. That the first Marxist revolution occurred in Russia, not Germany as Marx had predicted, and that it lost many of its admirers after Lenin’s death, did not deter Lukacs from developing the basis for what feminists nowadays call a “standpoint” theory oriented toward groups that combine centrality to and alienation from the means of production of society. Whichever group occupies such a position is potentially the party of revolution.

**LUMENPROLETARIAT**

The word *lumenproletariat* means literally “ragged proletariat.” In the view of Karl Marx (1818–1883) and Friedrich Engels (1820–1895), the lumpenproletariat consists of people who subsist on the margins of society and scavenge a living from illegal or semi-legal activities, such as prostitution and petty thieving, and the underworld involved therein. The attitude of Marx and Engels to this group is extremely negative. In the locus classicus of the *Communist Manifesto* (1848), they are described as “the dangerous class, the social scum, that passively rotting mass thrown off by the lowest layers of old society” (McLellan 1977, p. 229). While such a group might be swept into joining the proletarian cause in a revolution, “its conditions of life,” continued Marx and Engels, “prepare it far more for the part of a bribed tool of reactionary intrigue.” And this description found empirical confirmation in the role that Marx conceived the lumpenproletariat to have played in the 1851 coup d’état of Louis Bonaparte (1808–1873) in France.

The reason for this negative assessment of the lumpenproletariat by Marx and Engels can be found in their conception of the role of classes in historical development. A class was defined by its relationship to, and potential control of, the means of production. In ancient society, the ruling class owned the slaves; in feudal society, the king and the barons owned the land; in contemporary society, the capitalists owned the factories and the proletariat owned (and was compelled to sell) its labor. According to Marx and Engels, as history unfolded, each new class was swept to power by its ability to gain control over the ever-changing forces of production. In their own society, they foresaw the decline of the bourgeoisie due to inherent crises in capitalism and the coming to power of the increasingly class-conscious proletariat who, as the majority of society, would be able to organize the productive forces with which they worked for the benefit of all rather than the few.

In this optimistic scenario, the lumpenproletariat had no positive role to play. This was because they had only a negative role vis-à-vis the forces of production. Whereas the proletariat was intimately involved in the forces of production in that industrialization made them more numerous, more cohesive, and more antipathetic to their exploitation therein, the lumpenproletariat, being essentially rootless and venal, could have no clear historical destiny.

This view found some confirmation in the 1851 coup d’état of Louis Bonaparte. It is in his analysis of the class context of this coup, titled the *Eighteenth Brumaire of Louis Bonaparte* (1852), that Marx most fully described his view of the lumpenproletariat. In a period of French history where neither the rising proletariat nor the declining bourgeoisie could attain political power, the lumpenproletariat could come to dominate by selling itself to

Louis Bonaparte, who was “an adventurer blown in from abroad, raised on the shield by a drunken soldiery, which he has bought with liquor and sausages and which he must continually ply with sausage anew” (McLellan 1977, p. 317). Louis Bonaparte could achieve this by relying on the army, which was itself “the swamp-flower” of the peasant lumpenproletariat.

Thus Marx’s view of the “ragged” section of the proletariat is very different from The Ragged Trousered Philanthropists (1914) of Robert Tressell’s (1870–1911) famous social realist novel. Being outside the process of production, the lumpenproletariat were not a class in the sense in which Marx and Engels usually used the term. Unlike the proletariat itself, the evolving industrial process subjected them to no revolutionary imperatives. They were either outside the process altogether or effectively counterrevolutionary in that they depended on the aristocracy or the bourgeoisie for their day-to-day existence.

The views of Marx and Engels are in sharp contrast with the anarchist tradition exemplified by, for example, their rival Mikhail Bakunin (1814–1876). For him, destruction was a precondition for building a new society and it was only those outside normal society who could be expected to have the necessary destructive urge that could go as far as terrorism and assassination. A more modern version of the view that salvation can only be found in the destruction was a precondition for building a new society. An advocacy of the revolutionary potential of the lumpenproletariat in the developing world can be found in Franz Fanon’s Wretched of the Earth. From a more negative point of view there are obvious echoes of the views of Marx and Engels in contemporary discussions of the emergence of an “underclass.”

LUMUMBIA, PATRICE
1925–1961
Patrice Lumumba was an outspoken African nationalist politician and first prime minister of the Democratic Republic of the Congo. He played a central role in the chaotic and hastily executed decolonization in the Belgian Congo in 1960. His assassination in 1961 by Belgian and American security services, who conspired with his Congolese political enemies, earned him a lasting place as an eloquent and courageous African champion against the excesses of Western governments and corporations.

Lumumba was born in 1925 in Kasai Province, in what was then the Belgian Congo. He completed primary school at a Catholic mission in 1943. He then worked as a clerk for a mining company before joining the Belgian Congo junior civil service as a postal clerk in Stanleyville. His life was typical of the evolute underclass of Western-educated and urbanized Africans, who kept the colonial system functioning. Despite his limited education, he was a good writer and brilliant orator.

The recession of the mid-1950s, which occurred as postwar Belgian sought to extract the maximum return from its investments in the Congo, led to high African urban unemployment and mounting discontent. In 1956 an evolute group in Léopoldville issued a manifesto calling for independence within thirty years. But both Lumumba, who led the Mouvement National Congolais (MNC), and Joseph Kasavuba, the leader of the rival Alliance des Ba-Kongo (ABAKO), called for immediate independence.

In response to urban riots in 1959, the Belgian government convened a conference in Brussels to determine the future of the Congo. Lumumba was placed under arrest and charged with inciting anticolonial riots, but when the MNC won a convincing majority at local elections, Lumumba was freed to attend the conference. Under pressure from the MNC, the Belgian government announced that general elections would be held in May 1960 for the newly created national and provincial assemblies, and for a national senate nominated by the provincial assemblies, with independence for the Congo on June 30, 1960. This would be the first experiment with democracy in the colony’s history.

Lumumba and the MNC advocated a unitary state with a strong central government. However, parochial interests, with the support of Belgian colonial interests, led to a profusion of ethnic and regional parties. The
MNC emerged as the largest party in the national assembly, but it was unable to govern without a coalition. Parochial tribal-based parties dominated the provincial assemblies.

Following the election, Lumumba became the independent nation’s prime minister, with Kasavubu serving as president. At the independence ceremony, Baudouin I, the king of the Belgians, praised Belgian colonialism, provoking Lumumba to a stinging impromptu critique of Belgian colonial rule and the exploitation of Western mining companies. In 1960, many in the West were shocked at an African publicly criticizing a European head of state. Coming in the midst of the cold war, it led the Eisenhower administration in America to view him as “pro-Communist.”

Within days, the Congolese army, drawn from the poorest and most marginalized segment of the population, mutinied. With the support of Belgian mining companies, Katanga Province declared its independence under Governor Moise Tshombe. Lumumba appealed to the United Nations for support, but the Security Council divided along cold war lines.

In September 1960, President Kasavubu dismissed Lumumba’s government, and Joseph Mobutu, the army chief-of-staff, arrested Lumumba. With the connivance of the U.S. Central Intelligence Agency and Belgian Security Lumumba was handed over to his enemies in Katanga, who murdered him on January 17, 1961.

The Lumumba legacy, like that of John F. Kennedy, has been shrouded by his untimely assassination in a mantle of unrealized promise. On one level, as the hapless victim of Belgian pride and American cold war paranoia, he was to be buried in the past and forgotten. Yet to many non-Europeans in America, the Caribbean, and Africa, the outspoken and charismatic African nationalist became a hero in the struggle against white racism and oppression, one of the martyrs of African liberation. His assassination and the widespread accusations (later confirmed) of American CIA involvement may have served as a warning to others in the anticolonial struggle, but to many ordinary black people, his murder was a confirmation of Western excess, duplicity, and racism. While Lumumba is a forgotten figure in the mainstream Western consciousness, to many black intellectuals his fate remains an indelible stain, a lasting reminder of Western neocolonialism.

LUNDBERG, ERIK
1907–1987

The Swedish economist Erik Filip Lundberg was born in Stockholm into an academic family. His father, Filip Lundberg, was a famous insurance mathematician. After studying economics and mathematics at Stockholm University, Erik Lundberg spent 1931 to 1933 in the United States, where he came under the influence of Wesley C. Mitchell (1874–1948), founder of the National Bureau of Economic Research. Mitchell inspired in Lundberg an interest in empirical research and a certain skepticism toward theory.

Despite this influence, Lundberg wrote a theoretical PhD thesis titled Studies in the Theory of Economic Expansion. This thesis earned him an international reputation among economists, but it was his only theoretical work. Lundberg’s thesis was completed in December 1936, a few months after the publication of John Maynard Keynes’s (1883–1946) General Theory of Employment, Interest, and Money. The disposition of Lundberg’s work was to some extent adapted to the then-current climate of discussion generated by the General Theory, but Lundberg was little influenced by Keynes’s book in any other sense. Lundberg, unlike Keynes, discussed both the production side and demand side of the economy, though Lundberg’s demand-side theory is similar to Keynes’s.

The starting point for Lundberg and for the Stockholm school was to a great extent the Swedish economist Knut Wicksell (1851–1926), though Lundberg was also influenced by Eugen Böhm-Bawerk (1851–1914) and Friedrich August von Hayek (1899–1992), according to whom capital was perceived as time consumption. Prior to Keynes, capital in this sense—that is, the length of the production cycle from raw materials through semi-manufactured products, investment products, and final products—played a role in explaining the business cycle.

Lundberg developed these lines of reasoning, in the spirit of the Stockholm school, into a sequence analysis. The combination of the accelerator principle, which determined investment and the multiplier via consumption, analyzed in a sequence of periods, was shown to...
cause instability in free market economies. This theory was dynamic in contrast with Keynes’s General Theory. Keynes analyzed the equilibrium situations in the economy and compared them with one another, while Lundberg analyzed processes in disequilibrium, namely, the development of the economic system over time. Paul Samuelson (1939) later simplified Lundberg’s theory in an elegant mathematical formulation.

After completing his doctoral thesis, Lundberg was drawn into analysis work and economic advisor tasks. He became head of the Swedish National Institute of Economic Research in 1946 and there developed inflation-gap analysis, based on his thesis. The inflation-gap hypothesis was measured, in a closed economy, as the difference between the aggregated effective demand and the production capacity at full employment. Lundberg’s years of empirical work resulted in 1953 in his great Konjunkturer och ekonomisk politik (Business Cycles and Economic Policy). This is a rich book with retrospective references to economic developments and discussions during the period between the world wars. The book also deals with the conditions for stabilization policy and the efficiency of regulated and planned economies compared to free markets. The significance of free market prices for efficient allocation of resources is also an important theme, one that aroused considerable interest in Swedish economic policy debates.

Lundberg’s Produktivitet och räntabilitet (Productivity and Rate of Return; 1961) studies the significance of capital formation for economic growth. Lundberg observed, for instance, that the small ironworks of Horndal in central Sweden had not made any net investment during a period of fifteen years, only investing in some maintenance work. Despite this, labor productivity increased by 2 percent a year. This is usually termed the Horndal effect and has since been studied under the label learning by doing.

Lundberg’s final major work was Instability and Economic Growth (1968). One of the issues in this book concerns the relationship, if there is one, between instability and growth. Lundberg found no such relationship.

Lundberg ranks as Sweden’s leading economist during the postwar period. He was chairman of the International Economic Association (1968–1971) and of the Nobel committee for economics (1974–1979). Because Lundberg was skeptical toward theory and worked eclectically, it is impossible to definitively establish his attitudes toward many social problems, apart from a deeply rooted economic liberalism. Lundberg had a pronounced sense of humor that could occasionally wound colleagues and students, but he was a good person and as a debater and advisor he epitomized integrity and honesty. He was not as successful as a teacher. His excess of approaches and ideas could easily confuse an inexperienced doctoral student, and few of his students continued on an academic path.

LUXEMBOURG INCOME STUDY

The Luxembourg Income Study (LIS), a research center and microdata archive, was founded in 1983 by Timothy Smeeding, Lee Rainwater, Gaston Schaber, and a team of multidisciplinary researchers in Europe. With support from the government of Luxembourg, LIS and its staff became an independent nonprofit institution in 2002. LIS is organized as a consortium of countries with financing from the national science foundations and other funders in the participating countries, as well as from the Luxembourgian government. LIS operations are governed by a board whose members represent the countries that provide data and financing. Janet Gornick, a political economist and sociologist based in the United States, became overall director of LIS in September 2006. Markus Jäntti, an economist in Finland, took up the post of LIS Research Director in 2005.

Janet Gornick, a political economist and sociologist based in the United States, became overall director of LIS in September 2006. Markus Jäntti, an economist in Finland, took up the post of LIS Research Director in 2005.

LIS has four goals:

1. To harmonize cross-national data, thus relieving researchers of this task, relying on an expert staff
that carries out the harmonization work and provides support services for users.

2. To provide a method allowing researchers to access these data under privacy restrictions required by the countries providing the data.

3. To create a system that allows research requests to be received and results returned quickly to users at remote locations.

4. To promote comparative research on the economic and social well-being of populations across countries.

In 2006, LIS included data from thirty countries, mostly in Europe and North America, but also including Australia, Israel, and Taiwan. The database contained over 150 datasets, organized into five time periods (known as waves) spanning the years 1968 to 2002. Wave six is due to come online in 2007. The data can be accessed in multiple ways. Researchers can write programs (in SPSS, SAS, or STATA) and send them via electronic mail directly to the LIS server; results are returned to the researcher, with average processing time under two minutes. There is also a web-based tabulator that allows users to construct tables using keywords. The LIS website provides a set of country-level indicators (known as Key Figures), including measures of inequality and poverty for each LIS dataset.

Extensive documentation for each dataset details technical aspects of the original survey, a record of the harmonization process, and institutional information on tax and transfer programs corresponding to the microdata variables. The LIS website also houses a comparative welfare states database and a family policy database; both contain an array of country-level policy indicators. These policy databases are widely used by LIS microdata researchers, who often seek to link policy variables to microlevel outcomes.

Reports based on LIS data have appeared in books, journal articles, and dissertations, and are often featured in the popular media. Each completed study is made available in the LIS Working Paper series, which numbered more than 450 papers by Fall 2006. The LIS website offers a Working Papers search engine, a complete set of abstracts, and most of the papers in full text.

Beginning in 2005, LIS expanded by adding a wealth data project. The Luxembourg Wealth Study (LWS) established a network of producers of microdata on household wealth and has, like LIS, harmonized the country-specific data into a common template, including comparable measures of net worth and its components. The LWS project will help to set guidelines for wealth data producers, as the LIS project has with income data.

LIS conducts annual training workshops that introduce researchers to the database and to cross-national research on wages, income, employment, and social policy. Between 1988 and 2006, more than five hundred scholars attended the workshops. LIS publishes a newsletter twice yearly, which is mailed to over 1,400 scholars in thirty-five countries.

The LIS microdatasets include income, employment, and demographic variables at the person and household level. Since LIS's inception, these microdatasets have been used by more than a thousand researchers in many countries to analyze economic and social policies and their effects on outcomes including poverty, income inequality, employment status, wage patterns, gender inequality, family formation, child well-being, health status, immigration, political behavior, and public opinion.

One of the most fruitful uses of LIS is for the study of income distributions across the richest countries of the world. Figure 1, derived from LIS’s Key Figures, summarizes income distributions in the LIS countries, using four measures of inequality (ratios of tenth and ninetieth percentiles to the median; the 90–10 “decile ratio,” and the Gini coefficient). This figure shows clearly that income distributions vary dramatically across countries, with variation seen at both the bottom and the top of the distributions. The figure also reveals loose clusters of countries, with lower levels of inequality in the Nordic countries, moderate levels in most of the continental European countries, and higher levels in southern Europe and in the English-speaking countries of Australia, Canada, Ireland, the United Kingdom, and, most especially, the United States. Notably, the former communist countries of eastern Europe report remarkably varied levels of income inequality.

LIS-based research has catalyzed changes in national policies—for example, British policy toward children, based on the work of Jonathan Bradshaw (Bradshaw and Chen 1997)—and has informed the United Nations, the Organization for Economic Cooperation and Development (OECD), and other major bodies about poverty, inequality, and employment outcomes across countries. Results based on LIS have been published in and lauded by Science (Butz and Torrey 2006), The Lancet (Lynch et al. 2001), and major academic journals in the fields of economics, political science, sociology, comparative public policy, and social measurement. A twenty-year anniversary volume, published by The Socio-Economic Review in 2004, further summarizes and explains the accomplishments of LIS (Smeeding 2004).

In 2006 LIS completed a comprehensive internal review of its data template and harmonization rules in order to improve the quality of the LIS data and to identify ways to increase cross-country comparability in response to changes in the previous two decades in the participating countries’ social policies and survey content. This review also led to a restructuring of the pen-

Thereafter LIS anticipated adding new datasets for all of the participating LIS countries; the newest wave of data (LIS’s sixth wave) was to include datasets from approximately 2004. In addition, LIS anticipated adding two new countries in 2007: South Korea and Japan. LIS also continued to work to bring in datasets from Portugal, New Zealand, and Turkey.

LIS’s income surveys have mostly come from high-income countries, as classified by the World Bank. Of the thirty countries participating as of 2006, twenty-one are high-income and nine are upper-middle-income (Czech Republic, Estonia, Hungary, Mexico, Poland, Romania, Russia, Slovak Republic, and Taiwan). One of LIS’s main priorities is to substantially increase the inclusion of middle-income countries. LIS intends to add microdata, at multiple points in time, from ten middle-income countries, including, for example, Brazil, Bulgaria, Chile, China, Indonesia, and South Africa.

Luxemburg, Rosa

1870 or 1871–1919

Rosa Luxemburg was a Polish Marxist revolutionary as well as the most relevant figure of the left wing of the German Social Democratic Party (SPD). Together with Leo Jogiches (1867–1919), she was the leader of the Social Democratic Party of the Kingdom of Poland. Breaking with SPD for its support of World War I (1914–1918), with Karl Liebknecht (1871–1919) she founded the Spartacist League (Spartakusbund), which became in 1918 the German Communist Party (KPD). Luxemburg was killed during the German Revolution of January 1919 by the paramilitary Freikorps, and by the order of the SPD chancellor Friedrich Ebert.

At Zurich University Luxemburg trained in law and economics. Indeed, many of her writings can be seen as an original and undogmatic reprise, critique, and development of Marxist critical political economy. By 1898 she was widely known for her trenchant and astute criticism of the mounting revisionism. In Social Reform or Revolution? (1899), the pamphlet she wrote against fellow SPD member Eduard Bernstein, Luxemburg strongly objected to the idea that capitalism was entering a phase of social and economic stabilization, with the end of class polarization and the attenuation of economic crises. Skeptical about the law of a tendential fall in the profit rate, she nevertheless defended “collapse theory,” but with too generic a reference to the lack of demand for commodities. She also stressed the essential link between money and value, justifying Marx’s notion of abstract labor as a real abstraction that actually comes into being with the unity of production and circulation.

She refined her argument after 1907 when she started teaching economics at the SPD party training center in Berlin. While preparing her lectures (which were posthumously collected in Introduction to Political Economy, 1921) she stumbled upon a difficulty in Marx. Luxemburg stressed what she called the “law of the tendential fall” of the “relative” wage—that is, of the share in the new value added that goes to workers—as the other side of relative surplus value extraction. In her view, though, the real wage may grow when the productive power of labor rises, the former always lagging behind the latter. Workers’ consumption is thus decreasing. Hence the question: Can capitalist investments fill the gap, and guarantee the smooth development of capitalist extended reproduction? In the Accumulation of Capital (1913) Luxemburg attacked Marx’s schemes of reproduction for promoting the illusion that in a “closed” setting capitalism can go on as “production for the sake of production,” and only disproportional crises can occur. Imperialism is seen as the consequence of the need to find new markets in non-capitalist areas. In the end, collapse due to lack of effective demand was certain: To avoid slipping into “barbarism,” socialist revolution was historically necessary.

She was fiercely attacked by critics who hit some blind spots in her formulation (which was written in haste in a few months) but missed the core of her position, stated most clearly in the Anti-Critique (written in jail in 1916–1917). Capital must be analyzed first of all as a macro-monetary circuit. Therefore, the issue at stake is that capitalists cannot recover from monetary circulation more than they injected into it, advancing either constant or variable capital. From this theoretical stance, the realization problem opens to the problem of finance as fundamental in a monetary production economy. This does not mean that Luxemburg’s view was correct: She discarded the distinction between “financial” and “industrial” capital, so her question could not have an answer. But her approach was more farsighted than her critics understood because she opened a new problematic (Bellofiore 2004).

Two interpreters who clearly perceived this were Joan Robinson (1951) and Michal Kalecki (1967). Robinson saw that the key issue in Luxemburg was that accumulation depends on the incentive to invest. Kalecki extended her position, showing that capitalism can find effective demand not only through net exports, but also through state deficit spending financed by the central. However, it must not be forgotten that in the last instance, crises erupt because of relative surplus value extraction: Although it induces a fall in the wage share, it also systematically upsets the conditions of equilibrium for capitalist reproduction, and then provokes disproportions and leads to a general
“glut.” Realization crises are failures to sell products at prices that recoup expected profitability due to inadequate aggregate demand. They are rooted in the dynamics of exploitation within the capitalist labor processes where valorization—that is, the production of surplus value starting from a given value—immediately occurs.

Customarily, Luxemburg’s position is labeled as determinist and under-consumptionist (which is clearly wrong), and her political perspective is condemned as spontaneous. A convincing rebuttal of this reading was put forward by Norman Geras (1976). What is relevant is Luxemburg’s opposition to Lenin. As Rossana Rossanda succinctly states, Luxemburg “never maintained that the masses could do without an organized vanguard which, for her, was identified with the party. However, the need for the latter was not derived from the absence of a political dimension of working class struggles as such, but from the objective fragmentation of these struggles, which a unifying strategy could alone overcome” (1970, p. 224).

In recent decades, interest in Luxemburg has shifted from discussion about her political, social, and economic thought to her pacifism, her love for nature, and her anticipation of some traits of contemporary feminism (Nye 1994).

LYING

People who are lying are trying to mislead others. If an attempt to mislead is conscious, entails misstatement of fact, and promises a payoff, it is usually considered a lie. Alongside its denotative meaning, lying is a pejorative term. In one investigation, college students rated the social desirability of 555 one-word descriptions of a person. According to these ratings, the most negative thing one can say about a person is not that the person is greedy, incompetent, prejudiced, or cruel. The most negative thing one can say is that the person is a liar.

Lying is related to other phenomena. Like deception, lying involves false communication. However, deception is a broader concept. Biologists have discussed deception by fireflies, possums, and plants, but few would claim that plants can lie. As lying is one type of deception, so are there many types of lies: lies of omission and commission, white lies, and high-stakes lies.

Lying has intrigued scholars for thousands of years. Theologians have debated the morality of deceit, and epistemologists have puzzled over opposite logical problems like the liar’s paradox. Lying has been a recurrent literary theme. Novelist have dazzled their readers with fictional deception and counterdeception; playwrights have captivated audiences with both dramatic and comic lies.

Social scientists’ interest in lying grew from a practical concern, the need to detect lies. In a 1917 Journal of Experimental Psychology article, Harvard doctoral student John Marston described his efforts to construct a lie detection technology, based on the premise that lying is accompanied by changes in blood pressure. Marston’s work gave rise to the polygraph, an apparatus that monitors several indices of autonomic functioning. Once polygraphs came to be used in examinations for truthfulness, the accuracy of this lie detector became a matter of scientific debate. Reviewing evidence on both sides of this controversy, the U.S. National Academy of Sciences concluded in 2003 that the polygraph detects lies at rates that are better than chance but imperfect. In the National Academy’s view, polygraph examinations are poorly suited for screening large populations of people that include only a small percentage of liars.

Soon after Marston’s psychophysiological venture, Hugh Hartshorne and Mark May developed methods for measuring character. In their 1928 book Studies in Deceit, Hartshorne and May reported many character tests, including a test for lying in children. This written self-report instrument asked children about conduct that is socially approved but rare. Thus, the child was asked, “Do you always obey your parents cheerfully and promptly?” Across thirty-six such items, some children claimed that they were always good and never bad. The authors maintained that these children were lying, while acknowledging that some might get high “lie scores” because they were exceedingly conventional. Hartshorne and May’s clever test inspired the inclusion of “Lie scales” on subse-
Lying

frequent self-report instruments. These seek to identify individuals who are falsifying their self reports.

Inspired by these pioneering efforts, social scientists have illuminated several aspects of lying: the demography of deceit, deceptive behavior, and veracity judgments.

DEMOGRAPHY OF DECEIT

Lying is most likely universal. It has been found in all cultures ever studied. In a 2003 investigation, Lawrence Sugiyma and associates reported some relevant cross-cultural evidence: that farmers in a preliterate culture perform as well as Harvard students on difficult reasoning problems, so long as the reasoning would prevent them from being duped in a social exchange. These results suggest that cheating is a pan-cultural component of social life. Indeed, evolutionists have attributed the large size of the human brain to selection pressures imposed by the ever-escalating Machiavellian intelligence of our ancestors’ scheming peers.

Psychologists have ventured estimates of the frequency of lying in everyday life. In one investigation, college students logged all the lies they told over a period of several weeks. Their records imply that the average student lies once or twice per day, once in every three to five social interactions. In another study, thousands of people from around the world were asked how many lies the typical person tells in a week. Their estimates varied widely, but the median estimate was that typical person lies seven times a week, or once a day.

Social scientists have analyzed deception at the institutional level. Historians have revisited large-scale military deceptions, like the Allies’ duping of Nazi Germany before the Normandy landing in 1944. Political scientists have described constraints on the use of duplicity by the intelligence services of democracies. Financial analysts have noted international differences in institutional corruption. According to Transparency International, an anticorruption organization based in Berlin, the most corrupt countries in the world in 2005 were Bangladesh and Chad. The least corrupt were Iceland, Finland, and New Zealand. Economic factors help explain international differences in corruption. Highly corrupt countries are poor and pay their civil servants poorly by local standards. Psychological factors may also play a role. Controlling for differences in income, countries are more corrupt if they feature a collective culture, rather than an individualistic culture.

Researchers have documented socioeconomic, racial, and family differences in lying. Armed with the character tests they developed, Hartshorne and May reported in 1928 that students from a low socioeconomic background are more likely to cheat than those from a higher background. In 2002 sociologists Judith Blau and Elizabeth Stearns reported a discrepant finding: that white students of high socioeconomic status are most likely and black students are least likely to condone cheating. Perhaps socioeconomic differences in cheating have changed over the years. In any case, there are family influences on deception. In 1982, a team of investigators measured 54 different personality traits on each member of 415 families in Hawaii. The researchers found that family members resemble one another in personality. This was expected. However, the researchers also found that family members resemble one another in the tendency to lie. Indeed, family similarities proved to be stronger on Lie Scales embedded within the investigators’ personality tests than on any of the other traits measured.

Social scientists have explored sex differences in lying. Although some have maintained that the sexes differ in the propensity to lie, it appears that a larger difference is in motives for deception. Women are more likely to lie to spare others’ feelings, while men more often lie out of self-interest. Relative to women, men are more suspicious of what they hear. Although there is little evidence that the sexes differ in the ability to discriminate lies from truths, women are more willing than men to accept politely what others say. Perhaps these sex differences reflect differential socialization experiences.

DECEPTIVE BEHAVIORS

Do people act in distinctive ways when they are lying? Are there behavioral signatures from which lying can be inferred?

Certain behaviors appear to accompany deceit on certain occasions. Medical researchers Alan Hirsch and Charles Wolf analyzed a videotape of Bill Clinton during Clinton’s August 17, 1998, appearance before a federal grand jury. While giving testimony that a judge later found to be false, Clinton displayed 20 of 23 putative signs of deception. Clinton, for example, made more speech errors when denying a sexual relationship with Monica Lewinsky than when answering perfunctory questions. While testifying about Lewinsky, Clinton showed a tendency to touch his nose—which the authors dubbed a “Pinocchio phenomenon.”

Although Hirsch and Wolf’s videotape analysis is certainly provocative, it reflects a single case. One wonders if the 20 behaviors that accompanied Clinton’s suspect testimony accompany most lies. To address this issue, psychologist Bella DePaulo and colleagues analyzed research data on 158 potential deception cues from 120 independent samples of lie- and truth-tellers. They considered facial cues, bodily cues, vocal cues, and verbal cues, organizing the evidence around a series of questions.

None of the 158 behaviors these reviewers examined is a perfect indicator of deception, always displayed when
a person is lying and never otherwise displayed. Even so, some cues bear a statistical relationship to deception. Compared to truth-tellers, liars are less forthcoming. They sound distant, appear tense, and convey a negative impression. Invariably actuarial, cues to deception vary to a considerable extent across situations, across liars, and across lies. Attempts to conceal fear may, for instance, be exposed by inadvertent signs of fear.

For lie detection, it is best to assemble evidence from multiple cues. German psychologist Gunter Kohnken has advocated a multi-cue approach for assessing the truthfulness of statements. This so-called Statement Validity Analysis has been used in Europe to evaluate legal testimony, particularly the testimony of children who allege sexual abuse. As a component of Statement Validity Analysis, the witness’s account of an event is checked against nineteen criteria presumed to be indicative of truthfulness. Criterion-Based Content Analysis (CBCA) deems as truthful, for example, witnesses who spontaneously correct themselves, admit a lack of memory, and recount events in a nonchronological order. Research studies corroborate the value of this content-based system, suggesting that CBCA can discriminate lies from truths with an accuracy of about 70 percent.

VERACITY JUDGMENTS

Alongside these research efforts are lay attempts to uncover deceit. Nonscientists make judgments of deception every day, and these judgments have consequences. Some business negotiations succeed and others fail because of the negotiators’ judgments of one another’s truthfulness. Some marriages end in a month and others last fifty years because of the partners’ beliefs about one another’s veracity. Lay judgments of deception have special significance in U.S. courtrooms, where jurors are the only lie detectors. Whenever witnesses give conflicting testimony, jurors must decide who is telling the truth. Thus under American law a defendant’s fate can hinge on her (or his) demeanor, and those who appear guilty are often found guilty.

Social scientists have investigated lay theories of lying. As they have discovered, people share beliefs about behaviors that accompany deceit. In a 2006 investigation a global deception research team found that the most common stereotype in the world about deception is that liars avoid eye contact. Residents of 75 countries said that liars avoid eye contact. Expressing this belief in 42 different languages. In response to the open-ended question “How can you tell that others are lying?” two-thirds of the respondents worldwide mentioned that liars avert gaze, and when they mentioned more than one way to tell when others are lying, they mentioned gaze aversion first.

Do people in fact avoid eye contact when lying? There is not much evidence to support this belief. In the findings reviewed by DePaulo and colleagues, people who are telling small lies show no tendency to avert gaze, and those who are telling bigger lies show only a weak gaze aversion. Even if there is a kernel of truth to the stereotype of the gaze-aversive liar, this belief is overdrawn. In a study by communications scholar Timothy Levine, college students were asked to rate the eye contact of peers they saw on videotape. When informed that the peers were lying, students perceived them to be avertting gaze.

Apologists for the American legal system contend that jurors are good at spotting deception. Unfortunately, research suggests that they are not. In 2006 psychologists Charles Bond and Bella DePaulo reviewed results from hundreds of experiments on people’s attempts to detect lies in real time with no special aids. Under these circumstances, people average 54 percent correct lie-or-truth judgments when 50 percent would be expected by chance. Although lie detection rates vary from study to study, much of the variation appears to be artificial, and the highest accuracy achieved by any group to date barely exceeds 70 percent. People usually presume that their acquaintances are telling the truth. Most people appear honest even when they are lying, and a few appear dishonest even when they are telling the truth. Individual differences in social competence may underlie differences in apparent honesty, psychologist Robert Feldman has found. Although skills at feigning honesty continue to develop through middle childhood, even three-year-olds can dupe adults, researcher Michael Lewis reports.

LYNCHINGS

Lynchings, illegal killings performed by groups of people under service to justice, race, or tradition, are a phenomenon seen across human history, from ancient cultures through contemporary ones, in pre-modern and modern Europe, Asia, Africa, and the Americas. Across cultures and eras, mobs have perpetrated lynchings in order to punish what they have perceived as behavior that violates societal norms. The definition of deviant behavior varies widely across cultural contexts, but most commonly lynch mobs have collectively murdered those they have accused of transgressions such as murder, rape, theft, the crossing of racial boundaries, or witchcraft. Roberta Senechal de la Roche argues in “The Sociogenesis of Lynching” (1997) that lynchings are more likely to occur in times and places where great social distance exists between deviants and those offended by their behavior. Lynchings have meaning as performances of collective violence, with mobs resorting to varying degrees of ritual, such as selecting a site of symbolic significance for a mob execution, the desecration of a victim’s body, or taking trophies or affixing signs to a victim’s corpse. With such ritualistic punishment, mobs have sought to emphasize particular values and the cleansing of a community of a victim’s alleged offense.

In the last several centuries, lynchings have arisen amid cultural conflict over changing legal systems, particularly when certain social groups have perceived themselves as alienated from or unprotected by the formal legal system. This was the case in the United States in the early to mid-nineteenth century, when lynching arose south and west of the Allegheny Mountains amid profound shifts in understandings of law and the criminal justice system. On the southern, midwestern, and far western frontiers of the United States in the 1830s, 1840s, and 1850s, white Americans seized upon lethal group violence unsanctioned by law—particularly hangings—to enforce mandates of racial and class hierarchy and to pull into definition tenuous and ill-defined understandings of social order and community. Collectively murdering Native Americans, Mexicans, African American slaves and free blacks, and working-class, nonlanded whites, white Americans rejected growing due-process legal reforms that offered the promise of fairness to the unpopular and powerless by protecting the rights of those accused of crimes. Invoking popular sovereignty, a notion stemming from the American Revolution that government was rooted in the people and could be reclaimed by them if their life, liberty, and property were threatened, lynchers imitated customary public punishments, the pillory and the gallows, even as reformers sought to abolish those institutions on grounds of humanitarianism and the maintenance of public order.

In the late nineteenth and early twentieth centuries, the ranks of lynchers included rural landholding elites and members of the rural and urban working classes. Significant numbers of lynchings occurred in the American West and Midwest. On the southwest borderlands of Texas, New Mexico, Arizona, and California, lynchers killed hundreds of Mexicans following the American conquest of those territories in the mid-nineteenth century and during the era of the Mexican Revolution in the 1910s. Beyond racial animosities, lynchings in the West and Midwest in the nineteenth and early to mid-twentieth centuries were motivated by criminal justice concerns and class prejudices revolving around the landed elite’s protection of property on the range. For instance, in California between 1875 and 1947, lynch mobs killed thirty-five whites, fifteen Mexicans, nine Native Americans, three Chinese, and two African Americans. In Iowa during the same era, by contrast, lynchers murdered twenty-three white men and one Native American.

However, the vast majority of lynchings in the United States occurred in the South, where mobs killed at least 2,805 persons, 2,462 of them African American, between 1882 and 1930. Stewart E. Tolnay and E. M. Beck (1995) document the leading states for lynching as Mississippi (452 victims), Georgia (381), and Louisiana (274). In the South in the late nineteenth and early twentieth centuries, lynching became a dramatic and frequent means for whites to seek to assert racial hierarchy over African Americans. Lynchings were concentrated in Cotton Belt and Gulf Plain counties that had seen significant recent black in-migration and where African Americans composed from half to three-fourths of the population. Lynchings often stemmed from violent disputes in which African American laborers had resisted the authority of planter-class whites or the indignities of the emerging Jim Crow system that segregated blacks from whites in public spaces. In some Cotton Belt jurisdictions, such as Caddo, Bossier, and Ouachita parishes in Louisiana, whites completely abandoned formal criminal justice institutions in favor of rampant lynching violence that reaffirmed white supremacy. In another social setting that became conducive to lynching, the growth of towns and cities mixed whites and blacks from different parts of the South. In these novel urban locales, thousands of whites sometimes participated in highly ritualistic lynchings of African Americans, as for example in the mob execution of Jesse Washington in Waco, Texas, on May 15, 1916.

Lynchings waned in the early to middle decades of the twentieth century, as antilynching advocates such as Ida B. Wells-Barnett (1862–1931), the NAACP (National Association for the Advancement of Colored People), and Jessie Daniel Ames (1883–1972) protested the injustices of mob violence. During the same decades, a significant southern, white middle class developed that opposed lynching and placed its faith instead in formal law, espe-
cially the death penalty. The U.S. House of Representatives passed several antilynching laws, but these were defeated in the U.S. Senate (on June 13, 2005, the Senate approved a resolution apologizing to the descendants of lynching victims for its historical failure to enact antilynching legislation). Brief surges in lynching in and outside of the South during World War I (1914–1918), the Great Depression, and World War II (1939–1945) raised fears that the practice could be reviving. However, lynching lost its public face in succeeding decades and went underground. In the latter decades of the twentieth century, small groups of whites murdered African Americans such as Emmett Till in northern Mississippi in August 1955; Michael Donald in Mobile, Alabama, in March 1981; and James Byrd Jr., in Jasper, Texas, in June 1998; as well as civil rights workers Andrew Goodman, Michael Schwerner, and James Chaney in Neshoba County, Mississippi, in June 1964.

In the late twentieth and early twenty-first centuries, lynchings occurred in such places as Latin America, sub-Saharan Africa, the Middle East, and the urban United States. In these locales, crowds of people have lethally punished alleged perpetrators of crime and have sought to explain their actions by citing ineffectual, distant, or corrupt criminal justice institutions.

LYND, ROBERT AND HELEN

Robert Stoughton Lynd was born on September 26, 1892, in New Albany, Indiana, and died on November 1, 1970, in Warren, Connecticut. In 1921 he married Helen Merrell, who was born on March 17, 1896, in LaGrange, Illinois, and died on January 30, 1982, in New York City. The two social scientists were best known for their community studies Middletown (1929) and Middletown in Transition (1937). During World War I, Robert, a Princeton graduate, turned to the ministry as the only institution working for spiritual values. After doing missionary work at a Standard Oil camp, he launched a muckraking attack on Standard Oil and John D. Rockefeller Jr. Both infuriated and impressed by Lynd, Rockefeller's chief aide for the social sciences, Raymond Fosdick, hired him to undertake a study on the church in a small city for the Rockefeller-funded Institute of Social and Religious Research. That work became the basis for Middletown.

THE MIDDLETOWN STUDIES

The Lynds began their study in Muncie, Indiana, in 1923 after choosing it as a representative American city. They quickly convinced the institute that one could not study the church in a vacuum but had to study it in an integrated fashion. They argued that one should study modern society as one would examine a primitive culture. Adopting the British school of functional anthropology, they concentrated on how the culture as a whole worked.

The Lynds split Middletown culture into six activities: getting a living, making a home, training the young, using leisure, engaging in religious activities, and engaging in community activities. Indebted most of all to Thorstein Veblen and his concept of pecuniary culture, the Lynds demonstrated how that culture dominated Middletown society. Everything followed from occupations and the consequent split into business and working classes. The way one earned a living dominated the culture from one's leisure time to one's church denomination.

Despite a lack of methodological training, the Lynds produced a sophisticated work of sociological research. They used well-conceived questionnaires for all organizations, interviewed representative samples of the population, and innovatively included the questionnaires in an appendix. Despite its methodological rigor, the institute refused the work because of its admitted biases and use of class perspective and for being, as William F. Ogburn noted, "too interesting to be science" (quoted in Lynd 1929).

As the Lynds attempted to gain control of the manuscript, Robert wrote the section on consumerism for inclusion in a book for the President's Committee on Social Trends, "Recent Social Trends." That piece followed the emphasis in Middletown on spending as dominating American life and used empirical techniques to argue for a change in society. The Lynds' works were among the first
not only to identify a consumer society but also to criticize it. After the release of the Middletown manuscript in 1928, it quickly became a best seller, winning praise from social scientists and the general public.

In 1935 the Lynds decided to restudy Muncie. They recognized that American sociologists had not conducted follow-up studies of communities and had paid insufficient attention to social change. Furthermore, they felt that the Great Depression would provide an excellent case study in how outside forces compel local areas to alter the status quo. They also realized that like most American social scientists of their time, they had overlooked the issue of social and political power.

In *Middletown in Transition* (1937) the coauthors discovered that Middletown in fact was not in transition. The most noticeable change, apart from the infusion of federal funds, was the total resistance of the community to change and the solidification of existing attitudes and institutions. In regard to power, the dominant Ball family had come to control even more of the economic and political structure. Producers of canning jars, one of the few products more in demand during the Depression, the Balls used their profits to buy up local bankrupt industries, contributed heavily to local charities, and controlled both political parties.

**INFLUENCE AND CRITICISMS**

Although the first Middletown book has had greater influence as a pioneering community study and historical source, the second volume also influenced later social scientists in the study of power. Although the concentration of power in one family in Muncie was not characteristic of larger communities, both Floyd Hunter’s study of Atlanta, *Community Power Structure* (1953), and C. Wright Mills’s *The Power Elite* (1956) saw power as being concentrated in small groups. Later pluralistic views such as Robert Dahl’s 1961 examination of New Haven, *Who Governs?*, questioned the Lynds’ results and biases.

The Middletown works represented the apex of the Lynds’ influence, although both of them continued to produce important theoretical works independently. During the 1950s both Lynds were accused of being Communists, and the Middletown books were removed from United States Information Agency libraries around the world. Both Robert and Helen were committed social activists and students of Marxism. They were also extremely popular teachers, Robert at Columbia and Helen at Sarah Lawrence. As fear of communism increased in the United States, several congressional committees subpoenaed the left-wing faculty to testify before them. While Helen testified before the Jenner Committee and kept her job, Robert suffered a nervous breakdown from which he never recovered. Their son Staughton would go on to become one of the leaders of the new left academia during the 1960s and 1970s.

**LYND, STAUGHTON**

1929–

Staughton Lynd, historian, radical political activist, and labor lawyer, was born on November 22, 1929, to the sociologists Robert and Helen Lynd, best known for their path-breaking Middletown studies. Like his parents, whose socialist views strongly influenced their son, Lynd pursued an academic career, graduating from Harvard in 1951 and obtaining a PhD in history from Columbia in 1962. Staughton Lynd, however, acquired notoriety not as a scholar but as a civil rights and antiwar activist.

Lynd came from a Quaker background. He was inducted into the U.S. army during the Korean War as a noncombatant conscientious objector, but discharged for his leftist sympathies. After leaving the army, Lynd and his wife, Alice Niles, joined the Macedonia cooperative community in Georgia. While teaching at Spelman College in Atlanta, Lynd became involved in the civil rights movement and in 1964 he organized Freedom Schools for the Student Nonviolent Coordinating Committee (SNCC) during the legendary Mississippi Freedom Summer of
In the fall of that year, Lynd moved on to become an assistant professor of history at Yale University, but his focus was on the fledgling movement against the war in Vietnam. He traveled to Hanoi in December 1965, along with fellow peace activist Tom Hayden and Marxist historian Herbert Aptheker. Lynd saw the trip as a mission to prevent the escalation of the war; it resulted in his passport being temporarily revoked by the State Department, though the federal government did not initiate criminal prosecution. The trip did, however, probably cost him tenure at Yale.

As an antiwar activist with the Students for a Democratic Society (SDS), he was involved in organizing mass demonstrations and providing support for income tax and draft resistance. When parts of the New Left embraced violence in the late sixties and early seventies, Lynd remained firmly committed to the ideals of nonviolent grassroots mobilization. In 1973 he enrolled in the University of Chicago law school, obtained a law degree, and in 1976 became a labor lawyer in Youngstown, Ohio, where he represented and helped organize steelworkers, sometimes in conflict with their unions. Legal strategies, in Lynd’s view, needed to be devised in close contact with working people and bolstered by radical direct action. His fields of activity have included the rights of retired and disabled workers, the struggle against plant closings, and efforts to create interracial labor alliances.

Lynd’s scholarly publications have always closely mirrored his interests and commitment as an activist, beginning with his 1962 dissertation on class conflict in the Revolutionary era. In addition, he has published books on slavery, oral histories of working-class activism, and, in 2004, an account of the 1993 prison revolt in Lucasville, Ohio. In 1998 Kent State University established the Staughton Lynd Collection, which includes materials from the 1930s to the year 2000.

Staughton Lynd has often been referred to as a Quaker influenced by Marxism. His socialism has always remained skeptical of dogma and tied to his strong belief in communitarian democracy, pacifism, and social justice. Not content to criticize American capitalism from the position of a middle-class intellectual, his life has been dedicated to helping empower poor people and minorities.

MACCOBY, ELEANOR
1917–

Eleanor Emmons Maccoby is a leader and innovator in theory and research on the social development of the child. The Barbara Kimball Browning Professor of Psychology Emerita at Stanford University, she received her BA from the University of Washington and her MA and PhD from the University of Michigan. After working at Harvard University for several years, she joined the Stanford faculty in 1958.

Maccoby's wide-ranging interests include theories of socialization, gender differences, and the effects of divorce on the child. She has examined the socialization process from early childhood through adolescence. With John Martin (Maccoby and Martin 1983) she has provided a virtually book-length review of the history of theories of child development within the family, relating these theories to current issues in socialization. In a highly influential early work, Maccoby and Carol Nagy Jacklin (1974) concluded that, contrary to popular conceptions, the evidence does not support the notions that girls, relative to boys, are more social, have lower self-esteem, are better at rote learning and repetitive tasks, are less analytic, are more affected by heredity, lack achievement motivation, and are more auditory. They did find preliminary evidence that girls have a greater verbal ability than boys, that boys excel in visual-spatial and mathematical ability, and that boys are more aggressive.

Basic to Maccoby's approach to socialization is the notion of interaction, taken in two senses: (1) face-to-face interaction in the process of socialization and (2) systemic interaction between biological factors and socialization. With respect to face-to-face interaction, Maccoby rejects the notion that socialization is a top-down process in which adults mold the essentially passive child. Rather, from the beginning there is true interaction between child and caregiver in the sense that each participant's actions are contingent, at least in part, on the actions of the partner. She expands significantly on the notion of bidirectionality most frequently attributed to Richard Bell (1968). The implication of bidirectionality is that the child is an active participant in his or her own socialization.

A second basic influence on socialization is the biological endowment of the child. In this context, Maccoby cites potential constitutional differences between boys and girls. These differences, in turn, influence the interaction of the child with others. An example would be the play separation of boys and girls in relatively unsupervised settings. Maccoby (1990) provides evidence that boys have a more rough-and-tumble style of play, termed a restrictive or constricting interaction style. This is aversive to girls, who have a more enabling or facilitating style (Leaper 1991). The result is play separation and contrasting socialization within these separated peer groups.

Maccoby and Robert Mnookin (1992) surveyed the effect of the current process of divorce on the child. They regard the institution of no-fault divorce as introducing a new social regime, the social and legal implications of
which continue to emerge. They conclude that, under the proper circumstances, the experience of divorce is not necessarily damaging to the child and that it is possible for life to proceed in a relatively normal fashion in these families.

MACHEL, SAMORA

1933–1986

Samora Machel was the first president of Mozambique following independence in 1975. He came to prominence in the 1960s during the struggle to end Portuguese colonial rule over Mozambique and was influential as a leader of the Mozambique Liberation Front, known as Frelimo for the Portuguese name, Frente de Libertação de Moçambique. Machel was born on September 29, 1933, to a rural family in southern Mozambique, and as a child he attended a Catholic mission school. He worked briefly as an orderly, trained as a nurse from 1952 to 1954, and was then employed as a nurse in the capital city, where he continued his nursing education. He and Sorita Tchaiakomo had a common-law relationship, and they had four children together. Machel married Josina Machel in 1969 during the armed struggle, and they had one child before Josina died in 1971. He married Graça Machel in 1975, and they had two children.

European nations began the process of granting independence to their African colonies in the 1950s and 1960s, but Portugal refused to end its colonial ties. As a result, the anticolonial movements in the Portuguese colonies, including Mozambique, were forced to operate clandestinely. Machel was greatly influenced by his experiences in the colonial medical services, where he witnessed racial divisions among workers and in the treatment of patients. He began attending secret nationalist meetings, and in 1961 he met and was deeply inspired by Eduardo Mondlane (1920–1969), who emerged as the leader of the Mozambican liberation movement. Within a year Machel had attracted the attention of the Portuguese secret police and had to leave Mozambique in 1963 when he joined Frelimo in exile in Tanzania. Machel joined the military sector of Frelimo and trained in Algeria. The first shots of the armed struggle were fired in 1964, and by 1966 Machel was the commander of the Frelimo army. His contribution to the development of Frelimo’s politics included his perspective that the independence struggle was not a racial issue of black against white, but was a struggle for freedom from the colonial system, an issue that continued to be contentious for many years. He was also a strong voice for socialism within Frelimo. After Mondlane’s assassination in 1969, Machel emerged as the leader of Frelimo and as president of Mozambique after the Portuguese fascist government was overthrown in 1974.

As president, Machel focused on unifying Mozambique and implementing an ambitious socialist program of reforms. Many enterprises were nationalized, education and health were dramatically expanded to serve ordinary Mozambicans, and new laws were introduced to support women, peasants, and others who had been marginalized under colonialism. But Mozambique was one of the poorest nations in the world, and it was difficult to sustain the planned changes. South Africa and Zimbabwe, both ruled by white-minority regimes in the 1970s, helped form and support an anti-Frelimo organization known as Renamo (for Resistência Nacional de Moçambique, Mozambique National Resistance). Machel found himself mired in an intractable guerrilla war as Renamo wrought extensive damage and destruction in Mozambique throughout the 1980s, ending with a peace accord in 1992.

Machel himself was a casualty of that war. In October 1986 he traveled to Zambia to participate in talks designed to bring an end to Renamo’s attacks. As his plane returned to Mozambique on October 19, it crashed under suspicious conditions. The plane, a Tupolev 134, apparently followed a beacon that the Soviet pilots believed would bring them to their airfield in Mozambique. Instead they crashed into a low hill inside South Africa at Mbuizini. Samora Machel and twenty-four other passengers, including other members of the government, were killed. South African officials claimed that the accident was a result of pilot
error. Most Mozambicans and many others believe that the crash was orchestrated by the South African apartheid regime. Despite several investigations, including testimony as part of South Africa’s postapartheid Truth and Reconciliation Commission, the exact circumstances of the crash have not been determined. More than twenty years later, President Armando Guebuza of Mozambique promised to further investigate Machel’s death, saying the government “would not rest” until the events that led to the death of his predecessor were clarified.

MACHIAVELLI, NICCOLÒ
1469–1527

The Renaissance political thinker Niccolò Machiavelli shocked Christian Europe by declaring that success in politics both necessitates and excuses any means used to achieve it. Born in 1469 in Florence to a family of some prominence but modest means, Machiavelli probably received a humanistic education in his youth, enabling him to become head of the Second Chancery of the Florentine Republic in 1498. This office brought him into close contact with a number of Renaissance potentates, inciting his penetrating mind to form a stern, indeed, cynical view of politics. After the republic’s fall in 1512, Machiavelli retired to his small landed property to study ancient writers and reflect on political affairs.

In 1513 Machiavelli wrote *The Prince*, a slender book in the traditional mirror-of-princes genre. His advice to princes, however, was far from traditional. Rather than exhorting them to practice the virtues, he encouraged them to “know how to enter into evil, when forced by necessity” (Chap. XVIII), on the grounds that “a man who wants to make a profession of good in all regards must come to ruin among so many who are not good” (Chap. XV). In particular, he argued that princes should not hesitate to use deceit and violence to maintain their state and secure their subjects. This advice transformed the European tradition of “reason of state” (Lat. *ratio status*, Fr. *raison d’état*). Whereas the medieval proponents of this tradition had considered the necessity to break moral rules for the common good to be exceptional, and thus reconcilable with a community of virtue, Machiavelli assumed necessary evil to be a regular aspect of politics, thus separating it from ethics. Machiavelli’s pithy maxims to this effect inspired generations of writers who called for strong measures to build the modern state, such as Gabriel Naudé in France and Johann Gottlieb Fichte in Germany. His approach also legitimized the ruthlessness of many statesmen who constructed it, including Thomas Cromwell, Cardinal Richelieu, Napoleon, and Mussolini.

From roughly 1515 to 1520, Machiavelli belonged to a circle of educated Florentines who met in the Oricellari Gardens and whose political views reflected the civic strand of Renaissance humanism. Drawing on the Aristotelian and Ciceroonian notion of citizenship, civic humanism advocated *vivere civile*, a life of intense involvement with public affairs, based on a humanistic education and framed by the institutions of a republic. Accordingly, they believed that men ought to deliberate wisely and serve capably in the offices of their city, while also practising the virtues, fostering concord, upholding liberty, and attaining greatness. Machiavelli’s exposure to this ideal prompted his major republican writings, the *Discourses on Livy* (c. 1518), the *Art of War* (1521) and the *Florentine Histories* (1525). In these works Machiavelli followed Renaissance fashion by taking the Roman republic as a model. According to Machiavelli, Rome maintained its liberty because it provided the commoners with a representative, the Tribune of the Plebs, who checked the tyrannical ambitions of the nobles with his power to veto any law and intercede with any action of the magistrate. Having this share in authority also made the commoners loyal enough to be armed for war in large numbers, enabling Rome to conquer a vast empire and attain unprecedented greatness. Moreover, Rome’s superior institutions were brought to life by the “good customs” of its citizens, allowing nobles and commoners to conduct their struggles over wealth and power without bloodshed and settle them by compromise.

The fact that civic humanism formed Machiavelli’s historical context has led a number of historians, most prominently J. G. A. Pocock (1975) and Quentin Skinner (1978), to conclude that Machiavelli was a civic humanist
himself. More penetrating analysis, however, reveals that Machiavelli’s republican writings rest on the same premises on human nature and ethics as The Prince, and they consequently propose corresponding maxims of action: “As all those demonstrate who reason on a vivere civile, and as every history is full of examples, it is necessary to whoever disposes a republic and orders laws in it to presuppose that all men are bad” (Discourses on Livy I.3.1). To found, as well as to reform a republic, an autocrat must therefore kill all those opposed to equality before the law. The good customs of the citizens are not only acquired by habituation under threat of punishment, they also are continuously degraded by their natural ambition and thus must be constantly renewed by exemplary and excessive punishments. Republics can execute policies more effectively than principalities because the majority can easily crush the minority, regardless of the harm done to individuals. Republics wage aggressive wars because the citizens need to satisfy their ambition abroad in order to mitigate conflict at home, and because security rests on striking first and acquiring empire. In other words, the “reason of state” forms the core of Machiavelli’s republican thought as well. He made this fact most explicit when he claimed that “where one deliberates entirely on the safety of his fatherland [i.e., republic], there ought not to enter any consideration of either just or unjust, merciful or cruel … one ought to follow entirely the policy that saves its life and maintains its liberty” (Discourses on Livy III.41).

Preference must therefore be given to the older view of Machiavelli as a bold, if not reckless, thinker who broke with civic humanism and the entire classical tradition by limiting political thought to what men do rather than what they ought to do. According to the German historian Friedrich Meinecke (1924), this impulse led Machiavelli to probe and reveal the full extent of the reason of state, while the philosopher Ernst Cassirer (1946) believed that it prepared the ground for the empirical approach of modern political science by making no distinction between legitimate and illegitimate states. According to the British philosopher Isaiah Berlin (1953), it led Machiavelli to undermine the Western belief in a cosmos unified by reason. The political scientist Sheldon Wolin (1960) noted that it made Machiavelli conceive of politics as a struggle between conflicting interests. The philosopher Leo Strauss (1963) observed that this impulse prepared Machiavelli to lower the ethical standards that human beings ought to follow. It was in these ways that Machiavelli lit the flame of modernity.

**MACHINERY**

The adoption of new machinery, as part of technological progress, is a very controversial issue in economic analysis. Many analysts consider technology, the diffusion of technology, and technological advancements, to be very effective in promoting and attaining economic progress. Others consider machinery and new technologies to be major factors in reducing employment and the de-skilling
of labor. These controversial views on machinery reflect the dual character of technology, which simultaneously creates and destroys labor positions.

Historically, the massive introduction of machinery in the production process took place with the advent of the capitalist economic system, and it was made possible by the subdivision and specialization of the labor process in the early stages of the capitalist mode of production. Adam Smith, in his famous example of the pin factory, showed very eloquently that the subdivision of the labor process into small consecutive tasks dramatically increases labor productivity and, more importantly, allows for the introduction of machines in the production process.

David Ricardo (1772–1823) was the first economist who discussed in detail the issue and consequences of technological progress in society. At first, he agreed with Smith that the mechanization of the production process is good for all social groups within an economy. The introduction of machinery increases productivity, lowers costs and, in competitive environments, lowers the prices of commodities. Eventually, all members of society benefit from the lowering of prices. Both the unemployment that is induced by technological change and the consequent substitution of capital for labor is only temporary, according to Say’s Law, which guarantees full employment in the economy.

Ricardo later revised his position, however, arguing that the introduction of machinery in the production process may not benefit the working class, since it may create conditions for permanent unemployment. This could occur if the expenditures on machines are not financed out of savings (new investments) but through the transformation of circulating to fixed capital (simple replacement of labor with capital). If the latter takes place, unemployment will rise and be permanent, and society will suffer. In both cases, however, Ricardo was supportive of a public policy favoring the introduction of machines into the production process. He argued that entrepreneurs will either search for higher profits by increasing productivity through technological progress, or they will invest in profitable projects abroad, rendering the domestic working class doomed to unemployment. Thus, the mechanization of the production process in an economy increases productivity and lowers per unit costs rendering the economy competitive in the international environment.

In Ricardo’s presentation of the question of machinery (as in James Mill’s), a certain confusion exists. At one point he argues that the substitution of capital for labor generates unemployment, but at the same time he stresses the benefits of genuine cost-reducing improvements in techniques. The theory that technological unemployment automatically generates compensatory adjustments was introduced by John Ramsay McCulloch in the 1820s. According to this approach, all technically displaced labor will necessarily be absorbed in the making of the machines themselves. This approach rests on the idea that, under perfect competition, innovations result in price reductions and an expansion of output. If demand is elastic, total receipts rise and the employer will increase his expenditures on either consumption or investment. If, however, demand is unresponsive to lower prices, the purchasing power in the economy still rises and consumers can acquire goods from other sectors, alleviating the increase in their sectoral demand. Either way, directly or indirectly, labor-saving machinery entails the expansion of output in an economy, which eventually causes the reabsorption of those displaced by machines.

Knut Wicksell (1851–1926), drawing upon compensation theory, argued that in analyzing the effect of labor displacement due to the introduction of machinery in the production process, the fact that unemployment creates feedback and domino effects in an economy should be considered. For instance, an increase in unemployment due to the displacement of labor will decrease wages and increase in profits. This rise in profits then brings about more investment and, by extension, more employment opportunities. In addition, the technological process introduced by machines increases productivity, lowers costs and prices, and eventually increases an economy’s demand and, most likely, employment.

An increase in labor productivity is important in the capitalist mode of production because the motive force of capitalism is the drive for profits. Quite simply, more profits can be attained if labor productivity rises. According to Marx, the inner nature of capital is its self-expansion (accumulation), which imposes on individual capitals a fierce competition for higher profits and survival. An increase in labor productivity leads to per-unit cost reductions. This allows the entrepreneur to act in the competitive arena according to the following two pricing options: (1) if the price remains the same, the capitalist can attain a higher profit margin and, eventually, more profits; (2) if the price declines, the entrepreneur can drive his competitors out of the market, thus enjoying the benefits of a higher market share. Hence, rising labor productivity becomes an essential condition for capital’s survival. Labor productivity rises if the amount of value that a worker produces in a given time rises. In today’s economies, with the existing physical and legislative barriers (labor laws) to workers employment, an increase in surplus value (which translates into potential profits for the capitalist) can take place primarily through the introduction of new machinery.

The introduction of machinery into the labor process has changed the nature of the labor process itself. These changes include the intensification of work, the introduction of methods that further promote the division of
labor, and the specialization and work rationalization that serve to simplify and standardize work so that it can be done in the least amount of time at the lowest cost to business. Technology is a particularly effective mode of getting workers to expend a greater amount of labor power while they are on the job. As a result, more output can be obtained by employing more capital and less labor. Prior to the 1960s, technology was applied primarily to industrial production and to manual work processes. These forms of mechanization reached their height in the automation of assembly lines and in “continuous-flow” processes, which raised industrial productivity enormously. The dominant form of new technology applied to work processes today is electronic technology, which allows a worker to operate several testing machines at the same time, thus serving exactly the same purpose as increasing labor productivity.

The introduction of machines in the production process has also changed the character of the labor process. Since the equipment makes all essential decisions, many skills are removed from the worker’s task, making the worker perform more repetitive functions at a more productive rate. Labor is in this way intensely divided and de-skilled. With the division of work and the mechanization of the production process, the real subsumption of labor to capital takes place. Once a new technology is finally rationalized and prepared for mass production, in the long run it will de-skill most workers. Hence, mechanization and de-skilling are the logical outcome of capital’s need to exploit living labor. However, there is no perfectly linear descent of skill levels of the labor force, because new technologies may also raise the skill level of certain groups of specialized laborers.

In the face of rapid technological change, workers have great difficulty in recognizing that changes in their jobs are caused by management’s desire for greater profits, and not by the machinery itself. The famous movement of Luddites at the beginning of the nineteenth century shows the impotence of the working class to realize the real cause of jobless economic progress. At that time, British workers were against the introduction of labor-saving machines, and in many cases they destroyed factories and machines. The fact is, however, that the historical tendency of capitalism is the growth of surplus labor (as a reserve army of unemployed). Moreover, the more skillful the labor, the more they will be unemployed, since the way capitalism introduces machinery in the production process encourages unskilled labor.

**MACHINERY QUESTION, THE**

The “machinery question” was developed by the economist David Ricardo (1772–1823) in the chapter “On Machinery,” he added to the third edition of *On the Principles of Political Economy and Taxation* in 1821. This question related, in his words, to the “influence of machinery on the interests of the different classes of society” and particularly to the “opinion entertained by the labouring class, that the employment of machinery is frequently detrimental to their interests” ([1821] 1951). Ricardo’s argument was presented as a recantation of his “previous opinion” on this question and marks the beginning of a debate that is still going on. This argument is based on the example of “a capitalist” with a £20,000 investment and particularly on how that capital is used over three succeeding years.

During the first year, a fraction (£7,000) of this sum is “invested in fixed capital,” the remaining part (£13,000) is “employed as circulating capital in the maintenance of labour.” Under conditions of simple reproduction, the gross revenue emerging at the end of the year must be £15,000, of which a part (£2,000, if the profit rate is 10%) is the net revenue (profit) of the year. The remaining sum (£13,000) is put back into the operation as the circulating capital of the next year.

In the second year, a process of mechanization begins, and half of the laborers previously employed in producing the gross revenue (wage goods plus profit goods) are transferred to the production of new machinery. Thus, the gross revenue emerging at the end of the year is £7,500, of which £2,000 is retained as the capitalist’s profit.
In the third year, the new machinery appears and is worth £7,500, or half of the gross revenue previously produced by the given number of laborers. Thus, the circulating (wage) capital of this year cannot be greater than £7,500 (half of the gross revenue produced in the previous year) minus the £2,000 profit, so that it actually falls to £5,500 from the £13,000 of previous years. Hence, the real wage rate (the wage goods given in exchange for one labor-year) falls to less than half of what it was initially.

Ricardo's argument cannot be understood without a number of qualifications. First, his "capitalist" is understood to be the only capitalist within a closed economy (a self-sufficient farmer or an industrial dictator) who cannot buy, but must produce, the new machinery. Ricardo's special assumption is that this production is realized without increasing the total capital employed—that is, without extra saving out of the capitalist's profit (which is unproductively consumed).

In addition, the "introduction of machinery" has two meanings. One refers to machinery still to be built, the other to machinery already built. While the former is the meaning adopted in the example above, the latter is adopted in other chapters of the Principles as well as in Ricardo's "previous opinion" which held that the introduction of machinery is beneficial to all classes of society. Since the two meanings reflect two equally legitimate assumptions, Ricardo's diverging conclusions in different phases of his life (as well as in different chapters of his principles) are not contradictory, so that his latest argument is an unnecessary recantation.

Ricardo's argument also requires that a distinction be made between national revenue (consumption goods) and national product (consumption goods plus instrumental goods), as well as between the consumption goods exchanged for productive labor (circulating capital in Ricardo's sense, or free capital in Jevons's sense) and the instrumental goods that assist labor in production (fixed capital in Ricardo's sense, or invested capital in Jevons's sense).

Ricardo's special assumption on savings as an unchanging magnitude is reflected in his idea that machinery be "suddenly discovered and extensively used." This assumption was designed to elucidate "a principle," not to explain current reality. This principle relates to the different role that capital plays in the demand for labor, depending on whether it is circulating (free) or fixed (invested). It also relates to the possibility that the gross revenue of a society (wages plus profits) may not increase—and may even fall—when its net revenue (profit) increases.

One interpretation of Ricardo's argument claims that what this is about, and what it warns against, is technological unemployment. This interpretation misses the change in the composition of national product (and of total capital) resulting from the (sudden) introduction of new machines and is focused instead on the impact on employment of a change in their technical coefficients. Ricardo's argument holds even if the new machines were identical to those already in use, provided they be produced without additional savings.

Another interpretation regards the "Ricardo effect"—by which "machinery and labor are in constant competition, and the former can frequently not be employed until labor rises"—as the core of Ricardo's argument. But the "Ricardo effect" deals with the causes, not the effects, of the introduction of machinery, and it is put forward, along with other qualifications, at the close of the machinery chapter in order to deny the "inference that machinery should not be encouraged."

Searching for episodes in economic history to confirm Ricardo's argument, the Nobel laureate John R. Hicks has alluded to the declining conditions of the working classes during the early phase of Britain's industrialization (1969). More properly, perhaps, Ricardo's argument could be used to explain the dramatic conditions of the working classes in the early phase of the Soviet Union's industrialization.

MACMILLAN, HAROLD
1894–1986

Maurice Harold Macmillan was the prime minister of Great Britain from 1957 to 1963. A member of a famous publishing family, Macmillan was born in Brixton, England, on February 10, 1894. He was educated at Eton and Oxford University, and served in the British army during World War I (1914–1918). Macmillan was elected as a Conservative to the House of Commons in 1924. During the Conservative governments of Stanley Baldwin (1867–1947) and Neville Chamberlain (1869–1940), he criticized their appeasement policies toward Nazi Germany. During World War II (1939–1945), Macmillan served as a civilian official in the Ministry of Supply and later as a British liaison to American forces in North Africa and the Mediterranean. In this position, Macmillan developed a friendship with American general and future president Dwight D. Eisenhower (1890–1969).

Consequently, Macmillan was determined to develop a more cooperative, harmonious relationship with the United States in cold war foreign and defense policies. Both Republican president Eisenhower and Democratic president John F. Kennedy (1917–1963) valued Macmillan’s advice and diplomatic support. Macmillan persuaded Kennedy to deliver Polaris nuclear missiles to Britain in 1962, advised Kennedy during the 1962 Cuban missile crisis, and helped to negotiate the 1963 Partial Nuclear Test Ban Treaty with the Soviet Union. Macmillan also oversaw the continuing dismemberment of the British Empire as such former colonies as Malaya, Kenya, and Nigeria became independent nations. He tried but failed to overcome French opposition to Britain’s application for membership in the European Economic Community.

In domestic and economic policies, Macmillan pursued a moderate course. He assured working-class Britons that his Conservative government would not dismantle the Labour-initiated welfare state and would manage it more efficiently. He also promised to promote economic growth through tax cuts and fewer regulations on business. Macmillan’s centrist yet reformist rhetoric and policies contributed to a sharp increase in the Conservative majority of seats in the 1959 parliamentary elections.

Disagreements among cabinet officials about how to solve Britain’s problems with its balance of payments and Macmillan’s unpopular wage freezes to control inflation contributed to the loss of Conservative seats in the by-elections of 1961 and Macmillan’s decision to make major changes in his cabinet in 1962. The growing disunity of the Conservative Party and declining support for Macmillan’s government were intensified by the Profumo affair of 1963. John Profumo (1915–2006), secretary of state for war, misled Macmillan and the House of Commons in March 1963 about his adulterous relationship with Christine Keeler, a showgirl who also had a relationship with the Soviet embassy’s naval attaché. Labour members of the House of Commons asserted that such a relationship by the secretary of state for war endangered national security in the cold war.

Macmillan retired from politics in 1964 and rarely commented on British politics publicly. During the 1980s, however, Macmillan was rumored to be displeased with some of Prime Minister Margaret Thatcher’s more aggressive privatizing and monetarist economic policies. Busy with the chairmanship of the Macmillan publishing firm, Macmillan became a peer in 1984 as the earl of Stockton and died in Sussex on December 29, 1986.

MACROECONOMICS

The field of economics is divided into two subfields: macroeconomics and microeconomics. Macroeconomics is the study of the economy as a whole. It examines the cyclical movements and trends in economy-wide phenomena, such as unemployment, inflation, economic growth, money supply, budget deficits, and exchange rates. By contrast, microeconomics focuses on the individual parts of the economy. It studies decision making by households and firms and the interaction among households and firms in the marketplace. It considers households both as suppliers of factors of production (labor, land, capital, entrepreneurship) and as ultimate consumers of final goods and services. It also analyzes firms both as suppliers of goods and services and as demanders of factors of production.

Because the economy-wide events studied in macroeconomics arise from the interaction of many households and firms, macroeconomics is inevitably rooted in microeconomics. When economists study the economy as a whole, they must consider the decisions of individual economic actors. For example, to understand what determines gross savings (a macroeconomic issue), they must think about the intertemporal choices facing an individual—in response to a certain change in interest rates on deposits, whether to increase or decrease saving by decreasing or increasing consumption (a microeconomic issue).

Macroeconomic events and the state of the economy affect all members of society. Businesspeople forecasting the demand for their products and services should anticipate how consumers’ incomes will grow. Pensioners and people living on fixed incomes have concerns about potential price increases that could affect the cost of living. Unemployed persons looking for jobs always hope that the economy will grow fast so that firms will increase their labor force. Even politicians are affected by the state of the economy, which could influence the outcome of presidential or congressional elections. For instance, in purely democratic societies, the popularity of political leaders currently in office could fade in the event of adverse macroeconomic conditions (e.g., high inflation and/or unemployment) because voters are keenly aware of such conditions and their potential impact. It is, therefore, no surprise that economic policy is always a primary issue of debate for candidates during campaigns.

MACROECONOMIC VARIABLES

Economists assess the success of an economy’s overall performance by studying how it could achieve high rates of output and consumption growth. For the purpose of such an assessment, three macroeconomic variables are particularly important: gross domestic product (GDP), the unemployment rate, and the inflation rate.

Gross Domestic Product The GDP equals the total value of goods and services produced in a country during a year. Economic growth is, therefore, a sustainable increase in the amount of goods and services produced in an economy over time. However, economic growth is different from economic development. Noneconomists usually make little or no distinction between the two terms, using them interchangeably. Going further than GDP growth, economic development can be defined as “a multi-dimensional process of change focused on the betterment of the community, state, and/or country … and aimed at producing more ‘life sustaining’ necessities such as food, shelter, and health care and broadening their distribution, raising standards of living and individual self esteem, and expanding economic and social choice” (Todaro 2005, p. 4).

Development theories have started to look beyond GDP per capita as a sole measure of development and to consider other measures, such as health-care availability, educational attainment, equality of income distribution, and political freedom. GDP growth, though necessary, is not a sufficient condition for economic development. Modern theories try to explore other requirements for sustainable economic development, including the availability of sound government policies and institutions, infrastructure, lack of trade barriers, and fair judicial systems.

Capital accumulation is an essential factor for economic growth and development, which typically involve large-scale investments in infrastructure, industry, education, health, and financial sectors. Simon Kuznets (1901–1985) argued that levels of economic inequality can change as countries develop and, hence, accumulate more capital. Presumably, countries at early stages of development have relatively equal distributions of income because levels of per capita income and capital are low. As a country develops, more capital is accumulated and income distribution becomes unequal in favor of the owners of capital. Eventually, more-developed countries move...
Macroeconomics

back to lower levels of inequality either directly, through social welfare programs and other redistribution mechanisms, or indirectly, through “trickle down” effects.

Macroeconomists usually try to evaluate the economy's growth and development performance either in comparison to other economies (cross-sectional analysis) or over time (time-series analysis). In other words, macroeconomists investigate why the economies of many developing countries in Asia, Africa, Latin America, and eastern Europe tend to grow at a slower rate than those of developed countries, and how the rate of economic growth for a certain country can be improved over time.

Although sustainable growth is always desired by economic policymakers, economies do not always grow steadily and sometimes undergo periods of slowdown or expansion. Slowdowns in economic growth are called recessions. Severe economic slowdowns are called depressions (e.g., the Great Depression). During recessions, aggregate incomes decrease, as does the demand for goods and services. As a result, firms realize less profit, more firms go out of business, and, therefore, job opportunities become scarce.

On the other hand, economies can sometimes grow unusually fast. These periods of rapid economic growth are called expansions, and particularly strong expansions are called booms. During an expansion, businesses witness increasing growth and, hence, profits; incomes are higher because more people get raises and promotions; and, as a result, the demand for goods and services increases, which causes firms to realize even more profits, and more job opportunities become available. Given their importance, macroeconomists have a keen interest in analyzing economic fluctuations and whether policymakers can (or should) do anything about them.

Unemployment Rate The second most important macroeconomic concept is the unemployment rate, which is a key indicator of the condition of the labor market. The unemployment rate is defined as the percentage of people willing to be employed at the prevailing wage rate, yet unable to find job opportunities. When the unemployment rate is high, work is not only hard to find, but also less rewarding as people already holding jobs might find it difficult to get wage increases or promotions. A low unemployment rate is an indication of good economic performance. Thus, keeping workers employed is always a chief concern of economic policymakers.

Inflation The third most important macroeconomic concept is inflation, which is an increase in the overall level of prices measured by the consumer price index. This index shows how the value of money changes over time. Inflation is one of the primary concerns of economists and policymakers because it imposes a variety of costs on the economy. When the inflation rate is high, the real value of money erodes. People on fixed incomes, such as pensioners who receive a fixed dollar payment each month, cannot keep up with the rising cost of living. Inflation also redistributes wealth among the population in a way that has nothing to do with merit. When there is a sustained period of inflationary pressure, lenders and workers lose while borrowers and employers benefit because many work and loan contracts in the economy are specified in terms of money. Another cost of inflation is that it discourages saving. The income tax treats the nominal interest earned on savings as income, even though part of the nominal interest rate merely compensates for inflation. This reduces the after-tax real interest rate, and hence makes saving less attractive.

International Trade Another major macroeconomic topic is international trade, which is the exchange of goods and services across international borders. Because modern economies are highly interdependent, macroeconomists often study the impact and desirability of free trade agreements. They also study the causes and effects of trade imbalances, which occur when the quantity of goods and services that a country sells abroad (its exports) differs significantly from the quantity of goods and services its citizens buy from abroad (its imports).

ORIGIN AND EVOLUTION

Until the 1930s, most economic analysis did not separate microeconomic behavior from macroeconomic behavior. The 1776 publication of The Wealth of Nations by the Scottish economist Adam Smith (1723–1790) marked the birth of classical economics. Along with Smith, the major representatives of this school of economic thought include David Ricardo (1772–1823), Thomas Robert Malthus (1766–1834), and John Stuart Mill (1806–1873).

Classical economists emphasized the optimization of private economic agents, the adjustment of relative prices to equate supply and demand, and the efficiency of free markets. The classical theory dominated economic analysis till the late 1920s. Its main presumption is that the economy works better when government intervention is kept at a minimum because the behavior of different economic agents tends to achieve self-interests that are consistent with the overall well-being of the economy. Classical economists believed that the market itself would correct for any economic imbalance or turbulence without the need for government intervention. Any disequilibrium in a single market would eventually result in an automatic correction via the interaction between the two sides of the market, supply and demand, with the help of price flexibility. This flexibility would always ensure that
macroeconomic equilibria in the national economy are a result of automatic equilibria (clearance) in single markets. Classical economists also believed that the utilization of more inputs of production can be translated into higher levels of national output and income.

The Great Depression that began in 1929 in the United States was the worst economic catastrophe in the country’s history. During the depression, the United States experienced massive unemployment and greatly reduced incomes. This devastating period caused many economists to question the validity of classical economic theory, which seemed incapable of explaining the Great Depression. Classical economists believed that factor supplies and available technology determined the level of national income. However, real income in the United States decreased by 30 percent between 1929 and 1933 even though factors of production and technology remained unchanged. Therefore, many economists believed that a new theory was needed to explain such a large and sudden economic downturn and to identify government policies that might reduce the economic hardship so many people faced.

The British economist John Maynard Keynes (1883–1946) revolutionized the way economists think with his book, The General Theory of Employment, Interest, and Money (1936). It was pathbreaking in several ways. The two most important are, first, that it introduced the notion of aggregate demand as the sum of consumption, investment, and government spending. Second, it showed that full employment could be maintained only with the help of government spending.

Keynes proposed that low aggregate demand is responsible for the low income and high unemployment that characterize economic downturns. He criticized the classical theory for assuming that factor supply alone determines national income and that prices are flexible. In contrast to the classical theory, Keynes asserted that, in the short run, changes in aggregate demand rather than aggregate supply influence national income. Moreover, automatic economic equilibria are not necessarily ensured in the Keynesian world. In fact, economic balance can only occur by chance. Consequently, government intervention is sometimes sought in order to correct for economic instability.

The work of Keynes remains a central point of reference even today because all economic schools of thought label themselves in relation to the ideas initially developed by Keynes in his General Theory. Since the breakdown of the Keynesian consensus in the early 1970s, macroeconomics witnessed the emergence of a number of competing schools of thought consisting of economists who share a broad vision of how the economy as a whole works. Two “new” schools in particular have been highly influential: the new classical and the new Keynesian. These new schools share the view that macroeconomic theories should be based on solid microeconomic foundations.

Most economists use the term new classical broadly to describe the many challenges to Keynesian orthodoxy that prevailed in the 1960s. New classical economists advocate models in which wages and prices adjust quickly to clear markets. More recently, many new classical economists have turned their attention to real business cycle theory, which uses the assumptions of the classical theory—especially flexible prices—to explain short-run economic fluctuations.

New Keynesian economists, on the other hand, believe that market-clearing models cannot explain short-run economic fluctuations, and so they advocate models with sticky wages and prices. New Keynesian research is aimed at explaining how wages and prices behave in the short run by identifying more precisely the market imperfections that make wages and prices sticky.

Even though they sometimes reach differing conclusions, the various schools of thought are not always in direct competition with one another. It is unlikely that one of the current schools of economic thought perfectly captures the workings of the economy. Rather, each theory contributes a small piece of the overall puzzle.

THEORETICAL, EMPIRICAL, AND POLICY SIGNIFICANCE

Like all scientists, economists rely on both theory and observation. Macroeconomists usually try to explain the economic world as it is and consider what it could be. For this purpose, they use many types of data to measure the performance of an economy. They collect data on incomes, prices, unemployment, and many other economic variables from different periods and different countries. They then attempt to formulate theories that could help explain these data. They try to answer such questions as: Why do incomes increase over time? Why do some countries have high rates of inflation while others maintain stable prices? What causes recessions and how can economic policy be used to reduce their incidence and scale?

The goal of studying macroeconomics, however, is not just to explain economic events but also to improve economic policy. Macroeconomic policies are government actions designed to influence the performance of the economy as a whole. By understanding how government policies affect the economy, economists can help policymakers do a better job and avoid serious mistakes.

The policy goals that macroeconomists typically associate with the discipline include economic growth, price stability, and full employment. Policymakers always face three fundamental macroeconomic questions: (1) How can the rate of economic growth be increased and sus-
tained? (2) How can unemployment be reduced? (3) How can inflation be kept under control? To find answers to these questions, policymakers can implement the tools of three major types of macroeconomic policy: monetary policy, fiscal policy, and structural policy.

The term monetary policy refers to the management of the nation's money supply (cash and coins, although modern economies have other forms of money such as savings and time deposits and money market mutual funds). Most economists agree that changes in the money supply affect important macroeconomic variables, including national output, employment, interest rates, inflation, stock prices, and the exchange rate. In almost all countries, monetary policy is implemented by a government institution called the central bank.

Fiscal policy refers to decisions that determine the government's budget, including the amount and composition of government expenditures and government revenues. The balance between government spending and taxes is a particularly important aspect of fiscal policy. When the government spends more than it collects in taxes, it runs a deficit, and when it spends less, the government's budget is in surplus. There is a consensus among economists that fiscal policy can have an important impact on the overall performance of the economy.

Finally, the term structural policy includes government policies aimed at changing the underlying structure, or institutions, of the economy. The move away from government control of the economy and toward a more market-oriented approach in many formerly communist countries, such as Poland, the Czech Republic, and Hungary, is a large-scale example of structural policy. Many developing countries have tried similar structural reforms. Supporters of structural policy hope that by changing the basic characteristics of the economy or by restructuring its institutions they can stimulate economic growth and improve living standards.

POLICY DEBATE
Different analytical approaches lead to different policy conclusions. For example, a Keynesian approach would have governments run a surplus during the boom period of business cycles and a deficit during a recession. On the other hand, classical economists would prefer that the government not intervene to correct for short-term economic fluctuations; they believe this will distort the way free markets function. Others argue that using taxation as a macroeconomic policy tool has no effect on the economy; rational individuals tend to save when they receive tax cuts because they expect the government to raise taxes in the future to pay off its deficit.

As articulated in Mankiw (2004), there are three unresolved questions pertaining to monetary and fiscal policies, each of which is central to political debates: First, should policymakers try to stabilize the economy? Second, should monetary policy be made by rule rather than by discretion? Third, should the government balance its budget?

With regard to the first debate on whether monetary and fiscal policymakers should try to stabilize the economy, proponents argue that policymakers should take an active role in leading the economy to stability. When aggregate demand is inadequate to ensure full employment, policymakers should act to boost spending in the economy. When aggregate demand is excessive and there is a risk of inflation, policymakers should act to lower spending. Such policy actions put macroeconomic theory to its best use by leading to a more stable economy.

As for the controversy on whether monetary policy should be made by rule rather than by discretion, advocates assert that discretionary monetary policy does not limit incompetence and abuse of power. For example, a central banker may choose to create a political business cycle by raising interest rates to help a particular candidate. One way to avoid such a problem is to force the central bank to follow a monetary rule that is flexible enough to allow for some unforeseen circumstances that could affect the economy. Critics of this view argue that discretionary monetary policy allows flexibility, which gives the central bank the ability to react to unforeseen situations quickly.

Finally, macroeconomists have long debated whether the government should balance its budget or run a deficit. Advocates of a balanced budget argue that future generations of taxpayers will be burdened by public debt if the government accumulates annual deficits in the present. Opponents of the balanced budget approach argue that the problems caused by government debt are overstated and that the future generation's burden of debt is relatively small when compared with their lifetime incomes. If public spending on education and health is reduced, for example, this could lead to lower economic growth in the future, which would certainly not make future generations better off.

Macroeconomics, Structuralist

Structuralism finds its roots in ECLAC, a United Nations institution created soon after World War II to compensate Latin American countries for being left out of the Marshall Plan. One of the founding fathers of structuralism is Raúl Prebisch, an Argentinean who was executive director of ECLAC from 1950 to 1963. Prebisch was critical of various economic doctrines, including the critical views advocated by Keynes and Kalecki, that failed to consider the particularities of developing countries.

After leaving ECLAC, Prebisch became the first director of the United Nations Conference on Trade and Development (UNCTAD).

Macroeconomics, Structuralist

Macroeconomics as taught in North American and European universities does not reflect the particular set of problems faced by most developing countries. Indeed, more than simply reflecting different stages of industrialization, underdeveloped—or developing—countries followed very different development paths altogether, characterized by foreign technology, independently of their production factors (excess workforce), structural heterogenous domestic production, and structural inflation. Structuralist macroeconomics in contrast addresses specifically the economic development of Latin America. Incidentally, “underdeveloped economies” is a term coined by dependendist theorists such as Mauro Marini (1975) and Dos Santos (1978), who were largely influenced by the work of Andre Gunder Frank. This theory states that backward countries could never fully develop since they lack a national bourgeoisie class that could lead the industrialization process. The Economic Commission for Latin America and the Caribbean (ECLAC), however, took a softer view, coining the term “developing countries,” which eventually could “catch up” with industrial countries (Amsden 1989).

This ideology, advocated in particular by the International Monetary Fund and the World Bank, spread through academic and policy circles in Latin America. These policies, known today as the Washington Consensus, were adopted by most governments with disastrous consequences, since they did not take into con-
consideration the specific set of economic problems facing Latin American countries.

Latin American economies are characterized by two overall macroeconomic problems: dependence on the external sector and technological backwardness. In turn, these can be expanded into the following six stylized facts (Pinto 1973):

1. Having been colonies, Latin American countries were open economies: They were subjected to certain external markets for which they produced specialized goods and services based on their comparative (absolute or relative) advantage: They supplied raw materials to capitalist economies and imported manufactured goods. They were price takers, with terms favorable to industrialized countries, for which overvalued exchange rates are an important instrument (Kregel 2004).

2. Exports are not linked to the structure of domestic production. As a result, developing countries are highly dependent on imports according to the dominant mode of production (the primary export model before World War II; the import substitution model from the 1950s to the 1970s; the secondary export mode from 1980 until now).

3. There exists an imbalance in the structure of production: Industrial participation increased rapidly without a corresponding change in the agricultural sector or in the production of know-how and technology suitable for their factors of production.

4. There exists an imbalance between the productive sector and other substructures of the economy. The infrastructure was inadequate for industrialization, and the process of finance switched from the external to the internal markets, without developing a deep financial system.

5. The external dependence on imports induced higher income elasticities of imports and exports, and a highly price-inelastic demand for imports and exports, requiring overvalued exchange rates to reduce costs.

6. Exchange rate devaluations are an important transmission mechanism that induces inflationary pressures via magnified exchange-rate pass-through effects to prices, along with unequal income distribution that undermines the purchasing power of workers. Devaluations come with reductions in nominal wages (Noyola 1957).

Another important structuralist is Lance Taylor (1979, 1983, 1991), who believed that institutions and their behavior were the main determinants of resource allocation. Influenced largely by ECLAC, he approached development by first identifying stylized facts. First, “sectoral distinctions” are required in any analysis of development. In particular, Taylor argues that we must distinguish on the one hand between traded and home-goods production sectors, both highly dependent on imports, and between the agricultural (or traditional) and industrial sectors on the other. Second, financial markets tend to be underdeveloped. Third, distribution and class struggles are key components of the story of underdevelopment. In turn, these “centers of power” (Taylor 1991, p. 5) influence pricing and production decisions. Fourth, “unresolved distributional conflicts” are the source of inflationary pressures. Fifth, dependency on imports makes the economy dependent on foreign exchange.

**MAIN ISSUES OF STRUCTURALISM**

Given these facts, macroeconomic structuralists developed two important concepts. The first is “structural inflation” caused by factors unrelated to demand. In particular, given the openness of Latin American countries, there is a magnified pass-through effect from variations in the exchange rate to domestic prices. Latin American countries historically have had external current account deficits requiring external finance to cover the balance-of-payments deficit. External public borrowing, however, shifted toward external private borrowing (debt) and bond and shares issuance in the 1980s and 1990s.

The second concept concerned the unequal terms of trade, based on the price inelasticity of demand for imports and exports, and income inelasticity of demand. As a result, exchange rate movements do not induce equilibrium in the current account, which can be attained only through economic stagnation.

With respect to external financing, Prebisch and other structuralists were against relying on foreign direct investment (FDI) as well as foreign private credits, for two important reasons. First, while it is true that initially FDI was an important source of external capital (1940–1960), capital outflows soon were much higher than capital inflows, thereby exacerbating the existing fragile balance of payments. Second, while foreign investment increased, the imported technology was largely unsuitable for Latin America. Fajnzylber (1990) argued that FDI was less of a black box than an “empty hole.”

As for external debt, there was not much concern in the 1970s when interest rates were kept low. However, once interest rates were pushed up in 1979, it had dramatic implications for Latin American countries. Initially, capital movements reversed (1980s) and exchange rates devalued, preventing Latin American countries from financing their balance-of-payments account. In the late 1980s, financial markets were liberalized, a process that
continued through the early 1990s. External financing shifted to the bond market, which induced the 1994 crisis and the Tequila effect, which increased foreign direct investment importance, although these were of a different nature. Now, foreign direct investments are principally in the form of cross-border acquisitions and mergers, proving equally as unstable as movements in the bond market.

**STRUCTURALIST POLICIES**

Given the above discussion, what are the principal structuralist policy proposals? While we can identify several, the more relevant and important ones include the following.

1. Following Keynesians, structuralists believe that the emphasis of policy should be output, growth, and employment. To achieve growth, however, structuralists believe that the state should play a vital role.

2. Growth can result only from placing the emphasis on the domestic, internal industrial economy rather than relying on the export sector. As such, policies aim at eliminating the countries’ reliance on foreign demand for their primary exports (especially raw materials). As a result, import-substitution policies, such as government-imposed tariffs on imports, are seen as important policy elements.

3. Because of the technological backwardness of many sectors, an industrial policy of improving production technologies in lagging sectors is crucial.

4. End the perception of “old colonies” and reevaluate the role of developing countries and their relationship with other countries.

**MACROFOUNDATIONS**

The macrofoundations of economic activity consist of institutions (rules, norms, laws, and conventions) that define the social context within which economic processes take place. These economic processes include individual decision-making, production, exchange, and the determination of aggregate output and employment. Note that macrofoundations as defined here are understood strictly as social structures that shape the processes responsible for generating both microeconomic and macroeconomic outcomes. This is not to overlook the fact that the latter, themselves, frequently provide a type of “macrofoundation” for the former. For example, the existence of involuntary unemployment creates a social context that can be expected to impact significantly on the behavior of individual workers.

Macrofoundations can differ between regions and over time. They play an important role in supplementing...
the price mechanism as a means of coordinating economic activity.

FROM MICROFOUNDATIONS TO THE MACROFOUNDATIONS OF ECONOMIC ACTIVITY

Economists have long been interested in the microeconomic underpinnings of economic decisions and outcomes. This “microfoundations” project deems individual decision making to be the root source of all economic phenomena, and hence the basic “building block” of all economic theory. But an important oversight of this project is that, as much as individuals create the societies in which they live, so too, does society shape and mold individuals—their preferences, habits, beliefs, aspirations, and so forth. For example, exposure to the customs and laws of North America causes individuals to habitually keep to the right when driving on the road, and to regard such behavior as normal. But exposure to the customs and laws of the United Kingdom would result in the same individuals habitually keeping to the left, and coming to regard this different behavior as normal. The macrofoundations project calls attention to the importance of the social context in which economic activity takes place, and the role of this social context as a determinant of economic decisions and outcomes.

In particular, the macrofoundations of an economy are understood to supplement the workings of the price mechanism as a means of coordinating economic activity. Keynesian macroeconomists have long doubted the capacity of the price mechanism to coordinate economic activity so as to automatically create full employment. The macrofoundations project goes further, pointing out that the price mechanism does not even suffice to ensure the orderly reproduction of the economy from one period to the next, at any level of economic activity. Hence the price mechanism alone cannot coordinate expectations if there is fundamental uncertainty about the future (including the future states of markets and the prices determined therein). Nor can it coordinate actions pursuant to conflicts of interest that occur outside the sphere of market exchange—for example, at the point of production. But the economy’s macrofoundations can assist in the coordination of both expectations formation and conflict resolution. By specifying behavioral procedures of the form “in event of x, do y,” they provide a source of information about likely future actions and outcomes, and hence a basis for forming expectations in what would otherwise be a world of behavioral flux. For example, it is easier for workers to predict their future income if their employer is committed to a convention of retaining employees on current terms regardless of trade fluctuations, than it would be if wages and employment were made contingent on the future state of the labor market.

Furthermore, macrofoundations can ameliorate conflict, by regularizing relations between parties with mutually exclusive interests. For example, the conventional authority that is vested in a production supervisor can be used to settle disputes amongst subordinate operatives that might otherwise create prolonged disruptions to a production process. (Note that this last example draws attention to the fact that institutions sometimes codify power relations. Some economists regard the latter—together with related concepts such as the class structure of capitalism and the associated unequal ownership of wealth—as also being part of the economy’s macrofoundations.) In this way, the macrofoundations of economic activity have been likened to a computer’s operating system, providing a stable macroscopic environment within which particular actions (in the case of a computer, tasks using specialized software; in the case of an economy, specific economic activities) take place.

THEORETICAL, EMPIRICAL, AND POLICY SIGNIFICANCE OF MACROFOUNDATIONS

The existence of macrofoundations poses several challenges for economic theory. First and most obviously, it raises questions about the level of aggregation at which economic inquiry should begin. Rather than starting with an isolated individual conceived *sui generis*, the existence of macrofoundations necessitates that consideration be given to the societal norms, conventions, laws, and so forth to which the individual is exposed if his or her decision making and behavior are to be understood. This, in turn, requires a search for the macrofoundations pertinent to different particular facets of economic activity (such as corporate behavior, the workings of the labor market, or the determination of macroeconomic outcomes). Some economists believe that what is necessary in this regard is appeal to stylized facts about the operation of actually existing economies. This means that the macrofoundations project can be associated with economic theory that is spatially and temporally contingent rather than universal.

The macrofoundations project has already had an impact on empirical inquiry, with studies suggesting that economic outcomes such as unemployment can be explained by means of exclusive reference to macroinstitutional variables. Finally, the concept of macrofoundations has important policy implications. It suggests that, rather than treating the economy as a given “state of nature,” policymakers can (and do) contribute to the constitution of the economy by creating institutions that add to its macrofoundations. These include laws governing the limits to and operation of markets, and conventions (such as
the Taylor rule in monetary economics) that determine the objectives and pursuit of policy interventions.

MADISON, JAMES 1751–1836

James Madison was born in King George County, Virginia, in March 1751 and died at “Montpelier,” his country estate, in June 1836. The fourth president of the United States, Madison was one of early America’s most significant contributors to the developing social sciences, especially through his political and constitutional thought and writings.

Madison was born into a prominent Virginia family, the first son of James Madison Sr. and Nelly Conway. Madison’s education began in King and Queen County, Virginia, where he was taught by Donald Robertson, a Scottish teacher who ran a school there. His education continued under the Reverend Thomas Martin, a private tutor who was a graduate of the College of New Jersey (now Princeton University), which Madison himself later attended, graduating in 1771. At Princeton, Madison was influenced in lasting ways by the college president, John Witherspoon (1723–1794), who had come to America in 1768 partly through the efforts of Benjamin Rush (1746–1813), who at the time was a young American medical student studying in Edinburgh. Madison stayed on at Princeton after the completion of his undergraduate degree to study with Witherspoon more closely. As his correspondence shows, by the time he left college Madison was clearly well acquainted with the major thinkers of Western political thought, including Plato (c. 428–47 BCE), Aristotle (384–322 BCE), Huigh de Groot (1583–1645), Thomas Hobbes (1588–1679), and John Locke (1632–1704), as well as the works of the Scottish Enlightenment, including David Hume’s multivolume History of England (1754–1762). Madison also came away from Princeton—as did many of his classmates—a fiery supporter of the building Revolutionary cause and with a desire to promote religious freedom.

CHAMPION OF RELIGIOUS FREEDOM

From at least the early 1770s Madison was known to have championed religious freedom in his home colony of Virginia, a subject to which in 1785 he contributed “A Memorial and Remonstrance against Religious Assessments.” There, Madison wrote:

Torrents of blood have been spilt in the old world, by the vain attempts of the secular arm, to extinguish Religious discord, by proscribing all difference in Religious opinion. Time has at length revealed the true remedy. Every relaxation of narrow and rigorous policy, wherever it has been tried, has been found to assuage the disease. The American Theatre has exhibited proofs that equal and compleat liberty, if it does not wholly eradicate it, sufficiently destroys its malignant influence on the health and prosperity of the State. (Hutchinson 1956, pp. 302–303)

FATHER OF THE CONSTITUTION

While Madison is remembered in the early twenty-first century as a champion of religious freedom and for his support of the separation of church and state, he is even better remembered for his instrumental part in the deliberations at the Constitutional Convention held at the statehouse in Philadelphia in the summer of 1787. That convention resulted in the drafting of the U.S. Constitution, a document that showed Madison’s imprint at many key points. It is for this that he is remembered as the “Father of the Constitution.” Part of that legacy was the “three-fifths” compromise, whereby, for the purposes of taxation and representation, five blacks were considered equivalent to three whites. Like Thomas Jefferson and others of their generation, the slaveholding Madison was not able to reconcile—even in his own mind—the political realities of slavery in eighteenth-century America with the Enlightenment principles of freedom and liberty.
It is also on related constitutional issues that Madison is best known as a social science writer. Madison (with Alexander Hamilton and John Jay) was one of the three authors who under the pen name of Publius composed the Federalist, a collection of eighty-five essays first published in 1787 in New York newspapers. It was written with an eye to assuring ratification of the Constitution, and Madison is thought to have written twenty-nine of the Federalist essays. His most famous papers were Federalist No. 51, No. 39, and No. 10, an essay on the causes, nature, and remedies for the problem of factions. In that paper Madison merged his intimate knowledge of Scottish Enlightenment texts, including Hume’s History of England, with his personal experiences of American social and political developments. Madison countered Charles-Louis de Secondat (Montesquieu, 1689–1755) and other European and American political theorists, who argued in a civic republican vein that republican government could not long exist in a large country such as the United States. Madison wrote:

Extend the sphere, and you take in a greater variety of parties and interests; you make it less probable that a majority of the whole will have a common motive to invade the rights of other citizens; or if such a common motive exists, it will be more difficult for all who feel it to discover their own strength, and to act in unison with each other. (Carey and McClellan 2001, p. 48)

Madison was also one of the principal framers of the Bill of Rights, the first ten amendments to the U.S. Constitution, which went into effect in 1791.

**MADNESS**

Every society considers some of its members to be “mad,” “crazy,” “insane,” or “mentally ill.” Regardless of the particular term that is used, the core aspect of madness lies in its incomprehensibility. Universally, when social action seems to lack purpose, intent, or reason, observers are likely to apply labels of madness to it. To say that incomprehensibility is the major criterion observers use to classify madness is not just to say that they fail to understand or empathize with a person’s motives. Rather, it implies that the behaviors of the mad seem beyond the realm of understanding. This lack of comprehensibility distinguishes madness from other types of behaviors that violate social norms. For example, murderers that stem from recognizable motives such as jealousy, quarrels, or vengeance are not viewed as signs of mental illness. Someone who randomly kills a stranger without any possible motive usually cannot be placed in any socially recognizable category of murderer, and is likely to be viewed as mad.

Historically, labels of madness were reserved for people whose behaviors fell well outside the boundaries of normal social interaction. Beginning with the earliest written records, madness encompassed behaviors that appear to be “without reason.” The ancient Greek philosopher Socrates (c. 470–399 BCE), for example, noted that the Greeks of his time “do not call those mad who err in matters that lie outside the knowledge of ordinary people: madness is the name they give to errors in matters of common knowledge” (Rosen 1968, p. 94). Since ancient times, societies have also recognized a second type of madness that features profound sadness and withdrawal that is not proportionate to the social circumstances of the sufferer. The eminent German psychiatrist Emil Kraepelin (1856–1926), writing at the turn of the nineteenth century, codified these two categories of disorder as dementia praecox or schizophrenia and manic-depressive or affective conditions, which remain as major types of disorders.

**SOCIAL RESPONSES TO MADNESS**

While the core meaning of madness as incomprehensibility is universal, the boundaries of this label, as well as the specific behaviors that fall within it, are culturally specific and highly variable. The social responses to people who are considered mad have diverged considerably across cultures and throughout time. The simplest social groups, where individuals are bound to a small number of kin and group members throughout their lives, typically respond to those they consider mad with sympathy and tolerance, and attempt to maintain them in the group with little stigma. The Yoruba of Ghana provide a typical example. “The majority of chronic schizophrenics in rural districts,” according to M. J. Field in Search for Security...
(1960), “are treated with such patient and sustained kindness by their relatives and tolerance by their neighbors that the prognosis for their recovery is probably better than it would be were they herded with other patients in understaffed mental hospitals” (p. 453).

With growing social complexity comes a lower tolerance for the aberrant behavior of the mad. Most Western societies have associated madness with unpredictability and violence and have shunned and excluded the mentally ill from social life. In ancient Israel, Greece, and Rome, for example, the mad often roamed through the countryside and were commonly mocked, ridiculed, and abused. Likewise, in medieval Europe, the mentally disordered did not participate in community life, were stigmatized, and often treated harshly. The French philosopher Michel Foucault (1926–1984), however, asserts in Madness and Civilization (1961) that before the seventeenth century madness was linked to wisdom and insight and “man’s dispute with madness was a dramatic debate in which he confronted the secret powers of the world” (1965, p. xii). While Foucault probably exaggerates the respect shown to the mad during this period, it is true that no formal institutions existed to confine the mad and they were left to roam the countryside at liberty, provided that they did not create disturbances.

The breakdown of social cohesiveness in Western societies resulted in a more dramatic exclusion of those who were viewed as mad. Confinement in mental institutions arose between the sixteenth and nineteenth centuries in western Europe and at the beginning of the nineteenth century in the United States. This growing segregation reflected growing urbanization, geographic mobility, and immigration that contributed to the breakdown of cohesive communities.

In the United States, the initial mental hospitals of the early nineteenth century emphasized what was called moral treatment that provided individualized and sympathetic care within small residential facilities. By the middle of the nineteenth century, however, mental institutions had become much larger and more bureaucratic. Under such circumstances, moral treatment became more problematic. The new profession of psychiatry developed around these formal institutions, and nearly all early psychiatrists had positions in mental hospitals. These facilities served as the central institution devoted to the care of the mentally ill until well into the next century. By the beginning of the twentieth century, their residents were often elderly, from impoverished backgrounds, and members of disadvantaged ethnic groups. Many stays were long term, and often persons who entered these institutions ultimately died within them. But some individuals passed through them for short stays and may have benefited from their experience. To be sure, mental institutions had serious flaws, including their huge size, overcrowding, geographic isolation, involuntary confinement, depersonalization, and coercive and custodial treatment. Nevertheless, they provided the most seriously ill persons an integrated range of services—housing, food, symptom management, medical treatment, a place for social interaction, and respite from stressful community conditions—in one centralized location.

Beginning in 1955, the use of mental hospitals to confine the mad began to break down in the United States as the average number of residents in state and county mental hospitals started to decline from a peak of 550,000 to 370,000 in 1969 to about 60,000 in 1998. Taking growing population size into account, the number of residents in state and county mental hospitals fell from 339 per 100,000 persons in 1955 to 91.5 in 1975 and to only 21 in 1998. A variety of factors led to the steep decline in the use of traditional mental institutions. The introduction of psychotropic drugs in the mid-1950s, political and legal movements devoted to stiffening requirements for institutional commitment, the expansion of the civil rights of mental patients, and the growth of community treatment all played a role. But the development of government entitlement programs, notably Medicare, Medicaid, Social Security Disability Insurance, and housing supplements, were the most significant facilitators of community treatment.

**EXPANDING DEFINITIONS OF MADNESS**

Until the end of the nineteenth century, the category of madness was largely reserved for people who behaved in bizarre and incomprehensible manners. At that time, the boundaries of this category began to undergo a dramatic expansion. Stimulated by the rise of psychoanalysis, outpatient treatment developed as a parallel system to inpatient mental hospitals. In contrast to the generally impoverished, poorly educated, and socially marginal persons who resided in mental hospitals, outpatient clients were often financially well-off, highly educated, and intellectually sophisticated. Over the course of the century, the type of problems associated with outpatient psychiatric care expanded from severe and disabling disorders to encompass people with problems of living, such as troubled marriages, wayward children, and lack of purpose in life. In contrast to the declining population of public mental hospitals, treatment in outpatient mental health settings in the United States increased by over twentyfold between 1955 and 2000.

A major change in the response to the mentally ill occurred in 1980 when the psychiatric profession codified hundreds of different mental illnesses in the *Diagnostic and Statistical Manual (DSM-III)*. This manual includes...
not only the sorts of incomprehensible behaviors that have always been viewed as forms of madness, but also numerous forms of emotional, behavioral, psychophysiological, and many other disorders that extend well beyond the traditional boundaries of madness. It reflected the idea that mental illnesses, like physical illnesses, were specific disease entities that were likely to have biologically based causes. The DSM's categories of mental illness have expanded to the extent that population surveys estimate that half of all Americans will experience some mental illness during their lifetimes, and over a quarter have some disorder at any given time. At the same time, there has been an explosive growth in the use of psychotropic medications. These medications, first introduced in the 1950s, have exponentially expanded to the point that 10 percent of women and 4 percent of men consume them in any given month. Indeed, three of the seven largest selling prescription drugs of any sort are now antidepressant medications.

MADNESS IN THE TWENTY-FIRST CENTURY

The concept of madness has simultaneously shrunk and expanded over the course of recent history. As mental illness has replaced madness as the term most likely to be applied to incomprehensible behaviors, fewer people experience exclusion, confinement, and stigma. The social distance between the mad and the normal has decreased with the growing emphasis on the similarities between mental and physical illnesses and on the perceived biological origins of mental illness. At the same time, this concept has expanded as more behaviors are regarded as signs of mental illness, more people are seen as suffering from this condition, and more individuals seek help from medical and mental health professionals.

The evolution of madness into mental illness has brought both benefits and costs. On the one hand, it has led to efforts to destigmatize the mentally ill and treat them less coercively, as well as to a growing understanding of the causes of and effective responses to these conditions. On the other hand, no adequate program has replaced the many services mental hospitals used to provide, and the most seriously ill do not receive adequate care in the community. In addition, the expansion of the boundaries of mental illness have medicalized many normal behaviors and led to an overconsumption of psychotropic medications. The responses to madness at the beginning of the twenty-first century are far better than for most of Western history, but still have much room for improvement.

MAFIA, THE

The Mafia is an organized crime formation with Sicilian roots; branches in France, Tunisia, and the Americas; and a recent presence in Russia and Eastern Europe. Its historical successes vis-à-vis other criminal groups, particularly in the United States, have made the word mafia (whose origin has never been convincingly traced) a brand name for organized crime. Recently repressed on both sides of the Atlantic, the Mafia, as such, may be on the wane, although reduced vigilance could allow a resurgence.

Intrinsically secretive and violent, organized crime is best known through criminal investigations, yet police models, influenced by concerns of state, pose analytical problems for social science research. Early interpretations of the Sicilian Mafia—for example, Gaetano Mosca’s article in the 1933 Encyclopedia of the Social Sciences—emphasized two aspects associated with Sicily’s western provinces, historically dominated by quasi-feudal latifundia: a “mafisti” attitude valorizing self-help justice, as expressed through the concept omertà (silence before the law); and localized bands known as cosche (singular cosca) dedicated to animal rustling, extortion, and occasionally kidnapping for ransom. Although the menace of violence accompanied these activities, most murders resulted from inter- and intra-cosca rivalry for “turf.” The surrounding “mafisti” attitude impeded investigations, as did the political connections of mafiosi who “made elections” as the suffrage expanded.

In the 1960s foreign scholars of Sicily, swayed by that decade’s profound distrust of policing institutions, wrote about mafia with a small m and without the definite arti-
cle. Rather than an *associazione a delinquere* (criminal association) with boundaries, rules and goals, mafia was the sum of individual mafiosi wielding power through private violence. In the 1980s and 1990s, however, innovative Sicilian prosecutors, responding to the Mafia’s assumption of a commanding role in trafficking heroin to the United States, “turned” several mafiosi into justice collaborators, eliciting ethnographically rich personal narratives. (Palermo-based Tommaso Buscetta was the first of these, offering testimony to the prosecutor Giovanni Falcone, who was assassinated in 1992.) This and a corresponding citizens’ antimafia movement encouraged new research, much of it by Sicilian scholars, which revealed the Mafia to have a greater institutional capacity than had been imagined before.

Antecedents of the Mafia date to the late 1800s in Sicily, when a newly unified Italian state sought to transform feudal and ecclesiastical holdings into private property, impose taxes, and draft soldiers, but without building institutions that could govern the resulting banditry and chaos. Self-anointed “mafias” filled the breach, claiming to restore order while earning revenue from manipulating disorder. Enterprises of many kinds were extorted for a *pizzo* (a “beak full”) as the price for protection, and pressed to distribute employment opportunities in ways that leveraged the racketeers’ local influence. Using their electoral clout, mafiosi also insinuated themselves with local, regional, and national governments, receiving licenses to carry weapons and “fix” inconvenient trials. Older, established *capi* (bosses) rarely went to jail, whereas younger *picciotti* (henchmen and enforcers) experienced incarceration as no more than a perfunctory interruption of their affairs. When criminal convictions occurred, the cosca functioned as a mutual-aid society, taking care of imprisoned members’ families. Prisons, in turn, were nerve centers of inter-cosca communication. (In contemporary accounts, generalized “mafism,” earlier defined as the integument of the Mafia, is downplayed as part of a racialized “myth of Sicily” and an obstacle to serious inquiry.)

The state’s tolerant stance toward the Mafia was reversed by Benito Mussolini, but after World War II mafiosi reemerged to protect influential landowners from restive peasants, intimidating and even murdering their left-wing leaders. In addition, they offered electoral support to politicians of the newly constituted Christian Democratic Party—a cold war accommodation that enabled the penetration of modern domains such as urban real estate and construction, public works, and the administration of the land reform enacted in 1950. In the 1970s mafiosi with strong transatlantic connections—among them Gaetano Badalamenti, a resident of a town near the Palermo airport, and the above mentioned Buscetta—oversaw the shift from Marseille to Palermo of labs for refining heroin.

The audacity of the early narcotics traffickers was a provocation to the *Corleonesi*, an aggressive Mafia faction named for the fact that its leaders—Luciano Liggio, his protégé Salvatore (Totò) Riina, and Bernardo Provenzano (famously fugitive for forty years)—hailed from the interior town of Corleone. Allying with powerful capi in the Palermo region, this coalition raised capital for drug deals through kidnapping, which was normally disapproved of by the Mafia, and waged a murderous “war” whose victims—the *perdenti*, or losers—included many relatives and associates of Buscetta. The Corleonesi also advocated and carried out assassinations of public figures, among them Falcone.

The depositions of justice collaborators in the antimafia trials of the 1980s and 1990s, amplified by recent research, shed new light on the Mafia’s social organization and culture. Territorially grounded, the cosca, or “family,” is to some extent kin-oriented, with membership extending from father to sons, uncles to nephews, and through the fictive-kin tie of godparenthood. Yet, becoming a mafioso is also a matter of talent. Sons of cosca members believed to lack “criminal reliability” are passed over in favor of promising delinquents from unrelated backgrounds, and members seeking to induct large numbers of their own kin are viewed with suspicion. In effect, the word *family* is metaphorical—an evocation of the presumed solidarity of kinship. Mutual good will is further induced by idiosyncratic terms of address and linguistically playful nicknames. In a rite of entry inspired by Freemasons in nineteenth-century prisons, the Mafia novice holds the burning image of a saint while his sponsor pricks his finger and, mixing the blood and ashes, has him swear an oath of life-long loyalty and omertà, against the penalty of death. (1960s researchers doubted the existence of such a rite; Mosca’s essay makes no mention of it.)

Within the cosca, senior bosses hold the elected leadership positions, distribute moneys accumulated through extortion, and are responsible for the behavior of those novice whom they have personally sponsored. The *picciotti* are expected to show deference, take greater risks, and funnel their earnings upward. Ambitious upstarts occasionally murder their patrons, however, and seize power. The gossip and treachery intrinsic to cosca politics are considered affairs of men; women are excluded not only from meetings, but also from banquets and hunting parties, where masculine identity is asserted and novices socialized into the practice of violence. Nevertheless, the Mafia wife is usually from a Mafia family, enjoys the refinements provided by her husband’s money and status, assists in hiding fugitives, and willingly shelters his assets from the confiscatory power of the state. Most Mafia
women know far more than they are free to discuss, even with family and friends.

Breaking with the past, contemporary scholars dispute the coscà’s autonomy. Similar to other fraternal organizations, multiple local chapters are shown to foster mutual recognition across a broad terrain—an asset for long-distance trafficking in cigarettes, narcotics, and, of late, clandestine sex workers and migrants. In the 1890s in the bandit corridor that straddled interior Sicily, mafiosi organized the theft and hidden slaughter of livestock for sale in urban markets (at one point, including Tunisia); in the orchards near Palermo, they controlled not only the protection of crops and water for irrigation, but also the movement of citrus fruit to the Brooklyn docks. Recent research further suggests a relationship between far-flung trafficking, generally more lucrative than neighborhood rackets, and the Mafia’s felt need to create structures and lay down rules at a translocal level. One example is the Capula, or “Commission,” set up to coordinate groups in the province of Palermo, and then throughout western Sicily, in the 1960s through 1980s, to which intermediate districts sent representatives. At first considered derivative of a U.S. Mafia Commission dating to the 1930s, it is now believed to have had a forerunner in a similar Sicilian structure, the Conferenza, at the turn of the twentieth century.

Knowledge of the U.S. Mafia initially expanded with Estes Kefauver’s Senate hearings in 1950 and 1951; the FBI’s 1958 analysis following the spectacular if accidental 1957 raid of a secret meeting in Apalachin, New York; the McClellan Committee hearings on labor racketeering, prompted by the same event; and the probes of Robert Kennedy, chief counsel to John McClellan and then attorney general (until 1964). Under Kennedy, the Justice Department negotiated the terms by which a low-level mafioso, Joe Valachi, would testify about his experiences in the Mafia—testimony that exposed, among other things, the illusive term cosa nostra.

More or less sidestepping these state-centered sources, social scientists of the time analyzed organized crime in relation to the difficulties faced by early twentieth-century immigrants—Irish and Jewish as well as Italian—as they tried to earn a livelihood, benefit from corrupt political machines, and resist being criminalized by racism. (In the case of Italians, racial stereotyping included accusations of membership in a mysterious “black hand” organization, and numerous lynchings; eleven Sicilians were victims of the largest mass lynching in U.S. history in New Orleans, in 1891.) Images in print media, film, and television further complicate social analysis. The novel The Godfather (1969) and its film versions (1970s), produced by Italian Americans upset with racial stereotypes, romanticize their subject for outsiders. Other films such as Martin Scorsese’s Goodfellas (1990), based on the 1985 book Wiseguy by journalist Nicholas Pileggi, and the television serial The Sopranos (in which Italian Americans have also been involved) dramatize a model of masculinity that combines a haughty attractiveness with a dangerous readiness to retaliate against any perceived offense with gratuitous violence.

In light of several new sources—autobiographies (albeit self-serving) like Joseph Bonanno’s (1983); complex investigations pursued under the Racketeer Influenced Corrupt Organizations (RICO) statute of 1970; collaborative investigations with Italian authorities, unraveling, for example, the “pizza connection” network of heroin delivery to the East Coast and Midwest; telephone intercepts; and the impressive reporting of dedicated journalists—organized crime is now analyzed less in relation to impoverished immigrant communities and more in relation to New World opportunities attracting already experienced racketeers from abroad (who, in the case of Sicilians and southern Italians, made voyages back and forth, tending to affairs and, especially during the fascist period, evading surveillance). Underlying the opportunities was an American dynamic of race and class: As WASP elites enacted rigid laws to interdict “vices” associated with newcomers, vast black markets took shape—for drugs, prostitution, gambling, and most spectacularly, alcohol, prohibited from 1919 to 1933 by constitutional amendment.

Immigrant Italian communities were assets to the racketeers who came—a source of recruits for smuggling operations and easily conditioned to respect omertà. New York, with a million Sicilians and southern Italians by 1920 (not to mention the large number who worked on the Brooklyn waterfront), became the center of gravity for the U.S. Mafia. Yet the immigrant communities also suffered from having to harbor predatory entrepreneurs. Nor did they circumscribe figures such as Nick Gentile, who migrated from Sicily in 1905, joined a “family” in Philadelphia, sold fraudulent goods in Pittsburgh and Kansas City, trafficked heroin in New Orleans and Texas, and bootlegged liquor from Canada to Milwaukee and San Francisco. His close associates—Alfonse “Scarface” Capone in Chicago and, in New York, Joe “the Boss” Masseria and Charles “Lucky” Luciano—were also well-connected. A competing New York faction led by Salvatore Maranzano, the youthful Bonanno’s patron, had especially strong links to Castellammare del Golfo, a Sicilian town with a history of Mafia involvement in citrus exports.

Following prohibition, the most telling instance of New World opportunities attracting Old World mafiosi developed out of the 1956 Narcotics Control Act. Concerned about mounting drug arrests—aware, too, of
the pending loss of Havana, Cuba, (playground of Jewish
mobster Meyer Lansky and the Tampa mafiosi Santo
Trafficante, senior and junior), as a point of entry—
Bonanno led a delegation of American capi to Palermo
where, at a strategic meeting at the Grand Hotel of the
Palms in 1957, they franchised out to a select group of
Sicilians the business of distributing heroin throughout
the United States—a harbinger of Badalamenti's and
Buscetta's audacity, and of the pizza connection.

Money earned from protecting and trafficking in ille-
gal “vices” has helped American mafiosi colonize many
fields: loansharking, especially to addicted gamblers; Las
Vegas casinos and tourism; trash-hauling and construction
companies; coin-operated slot machines and laundromats;
and schemes for kickbacks, extortion, truck jackings, and
cargo theft and no-show jobs at ports, airports, wholesale
markets, convention centers, hotels, and restaurants.
Quickly accumulated capital has also been important in
bribing police and prosecutors; insinuating the Mafia into
municipal politics; penetrating labor unions; and paying
for first-class trial lawyers. However, with its heady possi-
bilities for risk, vice-related crime takes a large toll in vio-
ence. During the Prohibition Era, Sicilian bootleggers
and smugglers both allied with and warred against “out-
side” Irish and Jewish gangsters, near-outside Neapolitan
gangsters, and their own compatriots. Al Capone's
Valentine's Day massacre of a rival gang in 1929 in
Chicago, and the bloody “Castellammarese war” between
the Massaria and Mazarano factions in New York in 1930,
are landmarks of American Mafia lore.

Significantly for social theory, such crises, and the
unwanted attention they draw, prompt peacemakers to
push for higher-level organizational innovations. Thus in
1931, Luciano negotiated the systematization of five
Mafia “families” in New York, each with an elected capo,
an appointed consigliere, several subgroups or “crews,” and
a ceiling on new initiates. (More could join only upon the
death of existing members, which greatly enlarged the cat-
egory of Mafia “wannabes.”) The five heads, together with
Capone of Chicago (the next-largest hub of Mafia activ-
ity, after New York) and Stefano Magaddino, a Bonanno
relative in Buffalo, agreed to form an overarching
Commission to rule on pending murders. Articulating
territorial power with the far-flung entrepreneurial activi-
ties of individual mafiosi, this body pledged to meet with
bosses from across the country every five years. (The
Apalachin meeting took place during an off year, in part
to assess the 1956 Narcotics Act.) This was the
Commission that many believed inspired the Sicilian
Capo—perhaps via the 1957 meeting at the Palms—
until the discovery of the much earlier Conferenza.

By the 1930s the U.S. Mafia had surpassed other,
mainly Jewish and Irish, organized crime formations in
both firepower and discipline, yet its very organizational
coherence was a source of destabilizing leadership strug-
gles, as illustrated by New York's Gambino family. Police
investigators concluded, although without bringing
charges, that in 1957 the family's namesake (not its
founder) Carlo Gambino, together with Vito Genovese,
arranged for the then-boss, Albert Anastasia, to be mur-
dered while receiving a shave at his favorite barbershop.
Anastasia is believed to have leveled his predecessor in
1951. Gambino died a natural death, but his anointed
successor (and brother-in-law), Paul Castellano, was
gunned down in 1985 on orders of the up-and-coming
John Gotti—who, in turn, was “ratted out” by a cocon-
spirator, Sammy “the Bull” Gravano, who turned state's
witness in the context of intensified antimafia pressure in
1988. Similarly, in their brutal assault on the perdenti, the
Corleonesi either ignored or manipulated the Capo, car-
rying out numerous murders without its permission and
with impunity, then took it over as an instrument of
repression.

MAGIC

In ancient times, the term magic referred to the doctrines and practices of the “magi,” a Zoroastrian caste of priests centered in Persia. The term meant “gift of God” in its original language, but as individuals claiming to be magi contacted Mediterranean cultures, it came to mean any itinerant specialist in fortune-telling or other forms of the occult. Europeans looked positively upon the magi because in the New Testament the magi were celebrated in Matthew's account of the nativity of Jesus. But by 500 BCE the term magi also had a pejorative sense as many impostors made a living by pretending to possess supernatural powers gained in the mysterious East. The ars magica, or “the practices of would-be magi,” usually meant the tricks of showmen, a sense that followed the word “magic” when it entered English. For this reason, in the most popular usage, a “magic” trick performed by a “magician” typically means an illusion performed on stage as contrived entertainment.

In a more objective ethnographic sense, however, the concept of magic is useful in describing a common form of vernacular belief, as well as an important emphasis in a variety of new religions. The twentieth century occult revivalist Aleister Crowley (1874–1947) defined magic in a quasi-objective sense as “the science and art of causing change to occur in conformity with will” (Adler 1986, p. 8). His practice, however, involved the use of rituals intended to “cause change” through the use of occult forces. Folklorists and anthropologists have likewise seen similar tendencies in a variety of cultures, and so magic could be defined more precisely as any traditional ritual that seeks to protect or benefit an individual through the private appropriation of supernatural forces.

During his research among Micronesian fishers (1914–1920), British anthropologist Bronislaw Malinowski found that magical practices were based on practical, utilitarian needs of those engaging in professions with high degrees of personal risk, particularly open-sea fishing. Malinowski argued that “where man can rely completely upon his knowledge and skill, magic does not exist,” while in activities “full of danger and uncertainty, there is extensive magical ritual to secure safety and good results” (Malinowski 1954, pp. 30–31). Subsequently, ethnographers found similar practices among other cultures with a high degree of personal risk (such as fishing, mining, or lumbering) or where success is largely due to unpredictable factors (gambling, sports competitions, or the law).

Most common forms of magic are simple, including watching for omens of a lucky or unlucky venture, preparing and carrying amulets intended to bring fortune, or engaging in simple rituals at the start of an activity. Folklorist Don Yoder saw many of these as forms of “folk religion” and argued that they included any religious or quasi-religious practice observed but not positively prescribed by the institutionalized sect to which one belonged. However, more elaborate, privately maintained magic-religious traditions have also survived in ethnic communities alongside these common omens and rituals. These traditions are often termed “ceremonial magic,” and involve complicated rituals and magical paraphernalia. The rituals are similar in structure to blessings and prayers carried out in religion, but as Malinowski noted, they are often pragmatic in intent, serving to ensure success in an individual's economic or private matters.

Practitioners of such rituals normally define their art as “natural” or “white” magic because the forces that they use are the same as those honored in their dominant religion and their functions are supportive of their communities’ core ethics. In addition, as sociologist Hans Sebald found in a 1978 study of witchcraft traditions in Franconia (a region in southern Germany), magic often served as a convenient alternative in complex family disputes where calling in legal or religious officials would have caused a scandal. Nevertheless, such traditions are viewed with considerable suspicion by mainstream religious authorities.

The conventional distinction between “black” and “white” magic derives from this longstanding tension...
between vernacular practitioners and the law. In fact, scholars agree that few explicitly “satanic” or explicitly evil magicians ever existed. Prosecutors of the early modern (1500–1700) witch trials obtained confessions describing explicit devil worship and evil magic, but these descriptions were certainly obtained by coercion and torture. Sound ethnographic studies show that virtually all practicing “magicians” claimed to be “white” witches whose rituals supported the religious and ethical values of their communities.

Jealous religious authorities considered all private magic rituals, however, to be unnecessary (the literal meaning of “superstitious”), foolish, and at worst, a potentially dangerous form of “black” magic. “There is Mention of Creatures that they call White Witches, which do only Good-Turns for their Neighbours,” the Massachusetts Puritan minister Cotton Mather said shortly before the outbreak of the Salem Witch Trials (1692), adding, “I suspect that there are none of that sort; but … If they do good, it is only that they may do hurt” (Mather 1689, p. 4). To be truly divine, that is, the exercise of supernatural powers needed to be limited strictly to institutionally approved specialists. Any use of allegedly “good” magic outside of orthodox religion was often defined as “black” magic for that reason alone. In addition, magical rituals that cast misfortune on an individual, or which explicitly call on demonic powers are the most strongly proscribed as “dark arts” by mainstream religions and, at times, by civil authorities as well.

The more elaborate traditions involve a belief that an unexplained illness or misfortune could be explained in terms of a curse cast by another person, deliberately or inadvertently. Hence the magic user’s first task was to diagnose the source of the inquirer’s problem, then to conduct a ritual intended to remove its influence and frequently, turn the curse back against the one who cast it. Such magical specialists also fabricate and sell fetishes intended to protect its purchaser. Often these traditions are complex enough that they need to be preserved in writing, either privately maintained manuscripts passed down in a family or circle of practitioners, or in print editions available from specialists. Among these “magic books,” the most notorious include the Germanic Sixth and Seventh Books of Moses and the Jewish qabbalistic Key of Solomon.

A further development in magic occurred in England during the 1890s when a group of academics revived the medieval European traditions of ceremonial magic as a new religious movement. The Order of the Golden Dawn attracted many followers, chief among them the Irish poet William Butler Yeats (1865–1939), whose writings include frequent references to magical rituals that he performed. Crowley’s Ordo Templi Orientis (O.T.O.) was another influential faction in this movement. Predictably, Crowley was repeatedly denounced by religious authorities as a “black” magician who dabbled in Satanism. Although Crowley, a vocal critic of orthodox Christianity, at times encouraged this image, the rituals he practiced were in fact not diabolical in nature or intent. Nevertheless, the popular image of an evil “black” magician whose powers are countered by a benevolent “white” magician has become a cliché in popular fantasy and children’s literature.

More influentially, in 1954 Briton Gerald Gardner published a manuscript titled “Ye Bok of ye Art Magical,” supposedly the record of rituals preserved by a secret coven of English witches. In fact, the manuscript was based on publications of the Golden Dawn circles, but Gardner’s writings inspired the growth of a vigorous “Neo-Pagan” religious movement that has developed into a strong alternative religion in both Great Britain and North America. A number of ethnographic studies of contemporary witchcraft revival (particularly anthropologist Sabina Magliocco’s 2004 study) show that the use of magic has had profound impact on its followers. Magic, Magliocco argues, is not simple make-believe but a powerful means of inducing spiritually transformative experiences.

The common perception of “magic” in terms of illusion or ignorance is therefore simplistic. Magical beliefs need to be seen in the larger context of their practitioners’ social and religious worldviews. Only by seeing a magical tradition as an integral part of a culture’s definition of reality can we understand why it attracts and maintains followers.

Magna Carta

Emerging as a thirteenth-century agreement between crown and aristocracy, the language of Magna Carta (literally, “great charter”) proved pregnant with meaning for later generations. The charter came to be seen as representing wider legal and political principles, especially those of lawful and limited government.

The first attempt to limit political power by a written charter was King John (c. 1167–1216), the Plantagenet ruler of England, Wales, Ireland, and much of northern France. A descendant of the Normans who had conquered England a century earlier, John would become the first to reside permanently in England. He was crowned king in 1199 and immediately faced competing claims on his French territories, not least those of King Philip II (1165–1223) of France. In a series of wars with Philip and his allies, John lost much of his continental holdings by 1204. The following years saw him invade successively—and more successfully—Scotland, Ireland, and Wales. To exacerbate these military demands, John fell foul of Pope Innocent II (d. 1143). In 1207 the king contested the pope’s nominee for archbishop of Canterbury, Stephen Langton (c. 1150–1228). As a result, the pope placed England under an interdict on religious worship, excommunicated the king, and sided with Philip.

In attempting to pay for his military activities, John imposed increasing financial demands on the Anglo-Norman aristocracy. Combined with complaints about royal interference with the administration of justice, the result was rebellion against the king. In 1212 John acquiesced to the pope, agreeing to surrender his kingdoms to the papacy as feudal overlord and repurchasing them from him. An invasion of England was narrowly avoided the following year when the French fleet was destroyed. John then invaded France in 1214 in the hope of reclaiming his territories there. He suffered a major defeat at Bouvines, resulting in the loss of most of his remaining continental possessions.

John soon faced additional problems within England. Encouraged by Archbishop Langton, the Anglo-Norman barons there remonstrated against the king’s financial demands and judicial interference. In May 1215 they took London by military force. A truce was sought and representatives met at Runnymede, a meadow west of London on the river Thames, in June 1215. After much discussion, they agreed to a document of compromises called the Articles of the Barons. This was superseded by the charter subsequently known as Magna Carta. Formally, Magna Carta was a royal letter written in Latin dealing with a wide variety of issues: the freedom of the church, feudal customs, taxation, trade, and the law. This was not the first attempt to limit political power by a written charter. In England, for example, the Charter of Liberties issued by Henry I (c. 1068–1135) predated Magna Carta by over a century. Magna Carta was also similar to contemporaneous continental charters and legislation. Many of its rules came from a common pool of European political and legal thought, not least the canon law of the church. In the short term, the most potentially radical element of Magna Carta was probably the provision for a commission of barons to ensure royal compliance. But this came to nothing. Contrary to subsequent interpretation, it had little to do with the lesser landholders or the vast peasantry of England.

John renounced Magna Carta almost immediately. The pope, too, issued a papal bull against the agreement because it had been imposed by force. Civil war returned. Numerous barons now aligned themselves with Louis (1187–1226), Philip’s son and later Louis VIII of France, who invaded England in May 1216 with a significant army. Louis subsequently occupied London, where he was received enthusiastically by the barons and was proclaimed king of England. John made some military gains, but died of dysentery in October 1216. With his death, the barons’ complaints were less pressing. John’s nine-year-old son, Henry III (1207–1272), was seen as more politically malleable and was crowned English king. His regent, William Marshall (c. 1146–1219), one of the signatories of Magna Carta, revised and reissued the document in November 1216. Marshall was also able to convince most of the rebellious barons to renew their loyalty to the crown, ending the war. In 1217 a treaty was signed, and Louis left England. Another revision of Magna Carta that year separated the document into two sections: a brief Charter of the Forest concerning the royal forests, and the remaining text, the larger Magna Carta. Henry III reissued a still shorter version of Magna Carta in 1225. This version was confirmed by Edward I (1239–1307) in 1297.

The vague wording of Magna Carta, combined with changing social structures, meant that its text was continually reinterpreted. This is already evident in the fourteenth century. In general, the charter was largely ignored for centuries. By the seventeenth century, however, it took
on greater significance in conflicts between king and Parliament. Lord Chief Justice Edward Coke (1552–1634) was especially important in popularizing the belief in Magna Carta’s wider constitutional principles. With parliamentary ascendancy in the late seventeenth century, it continued to play an important role in debates both in and out of Parliament. In the eighteenth century, Magna Carta served as a touchstone for American independence and constitutional government. In England, the nineteenth century brought a more balanced assessment of its historical meaning and the removal of most of its antiquated provisions from English law.

The document retains a deeply symbolic importance throughout the English-speaking world. The American Bar Association erected a monument at Runnymede in 1957. In May 2003 the Australian Parliament opened Magna Carta Place in Canberra. In the early twenty-first century, four copies of the original charter remain: two in the British Library and one each in the cathedral archives at Lincoln and Salisbury.

MAHATHIR MOHAMAD
1925–

Tun Dr. Mahathir bin Mohamad, to give him his formal Malaysian designation, was the fourth prime minister of Malaysia. He was in power from 1981 to 2003, more than twenty-two years. Mahathir, an ethnic Malay and a Muslim, was born in 1925 in Alor Setar in northwestern Malaysia. He was trained during colonial times as a medical doctor at the University of Malaya in Singapore, graduating in 1947. As prime minister, he was widely credited with the transformation of Malaysia into a prosperous, fully employed, newly industrialized country that became a magnet for illegal immigrants from Indonesia, Burma (Myanmar), and Bangladesh. He is best known in the West as an outspoken advocate of “Asian values” and a critic of Zionism and Western hypocrisy. Mahathir is also widely seen as an authoritarian leader who was prone to cronyism and not adequately respectful of human rights.

Mahathir is a member of the United Malays National Organization (UMNO), the party that with its ethnic Chinese and Indian allies has ruled Malaysia since independence from the British in 1957. Mahathir was elected to parliament in 1964, but lost his seat in 1969 and was expelled from the party after criticizing the prime minister, Tunku Abdul Rahman (1903–1990). After readmission to the UMNO, Mahathir was again elected to parliament in 1974. He then became minister of education and from 1976 served as deputy prime minister. Throughout his career, Mahathir was both a strong advocate for the advancement of the indigenous Malay majority and one of the most vocal critics of Malay stereotyping. He held a strong conviction that racial harmony in Malaysia (and elsewhere) requires all communities to stand at approximately equal levels of prosperity, and he became frustrated when some sections of the Malay community encountered difficulties in their attempts to advance economically, despite the strong preferences afforded to them by Mahathir’s government.

During his twenty-two years in power, Mahathir was successful in creating a prosperous and sizable Bumiputra (literally, “sons of the soil,” that is, indigenous) middle class. During the colonial period, commerce and industry had been dominated by the Chinese and the professions by ethnic Indians. With Mahathir in power, the Bumiputra came to dominate Malaysia’s civil service, police, and military; they also gained a foothold in commerce, industry, and the professions. However, this progress was achieved at a substantial price. Quotas on non-Malay students in the universities, for example, prompted many non-Malay Malaysians to seek higher education in the United Kingdom, Australia, the United States, and elsewhere, and many never returned to Malaysia. In addition, emphasis on the national language in education led to a noticeable decline in the country’s standard of English, which eventually resulted in the partial reversal of language policies in education.

During Mahathir’s tenure, Malaysia evolved from a predominantly rural, low-income economy in the 1970s to a middle-income economy with full employment and social indicators similar to high-income economies. This was achieved through state-dominated capitalism, openness to foreign investment, and authoritarian political policies. Mahathir’s economic policies were always nationalist, although based on exports and guided capitalism. Following the 1997 Asian financial crisis, Mahathir’s government rejected the advice of the International Monetary Fund (IMF) and imposed a fixed exchange rate and capital con-
trols. He was widely criticized for this move, but the results were much better in Malaysia than in neighboring countries that had followed IMF advice, and Malaysia weathered the crisis with relatively little damage to either growth or investment. However, the crisis did produce difficulties with respect to undocumented immigrants, who flocked to Malaysia because of its relative prosperity and high demand for labor. Officials have attempted to repatriate migrants, amid the complaints of private-sector firms, particularly in construction, plantation agriculture, and low-skill manufacturing, about the impact of this policy on their labor forces. Mahathir also promoted a number of large-scale pet projects aimed at modernizing the economy and turning it into a high-tech center for the region. Some of these projects were eventually cancelled, with others looking more and more like white elephants.

Mahathir is perhaps best known in the West for his strong views on Asian values and his rejection of Western moral leadership. He argues that Asian societies place more value on the community than on the individual, and he considers the guidance of an authoritarian government as necessary to ensure stability and rapid economic development in Asian societies. Mahathir has also been a fierce critic of Israel. His relationships with the United States and other Western governments, most notably the United Kingdom and Australia, have often been tense, with much criticism flowing in both directions. American vice president Al Gore, for example, endorsed reform in Malaysia in a speech delivered in Kuala Lumpur in 1998, a speech that Mahathir described as “rude.” The Western critique centered on the authoritarian nature of Mahathir’s rule, particularly the curtailment of the press and other freedoms, draconian internal security laws, political repression, and harassment of rivals, notably Anwar Ibrahim, the former finance minister and deputy prime minister who was jailed on corruption and sodomy charges. Anwar had led a reform movement emphasizing the dangers of corruption and nepotism under Mahathir. Mahathir has been highly critical of the 2003 invasion of Iraq by U.S.-led forces and of the U.S. policy of detention without trial for prisoners held at Guantánamo Bay and elsewhere.

Mahathir has remained outspoken and influential in Malaysia since his retirement from active politics in 2003. In May 2006 he described his handpicked successor, Prime Minister Abdullah Ahmad Badawi, as “gutless” and “kowtowing” after Abdullah abandoned a project to build a bridge to replace the causeway joining Malaysia to Singapore. Many Malays and moderate Muslims elsewhere regard Mahathir with great respect for the economic achievements of his administration and his willingness to state independent views with eloquence and force.

In policy debates majoritarianism is most commonly invoked as a counterclaim to arguments for increased diversity or multicultural policies. The claims take the form of an identification of what “we,” the majority, stand for: “we are a Christian nation” or “we are an English-speaking nation” are common majoritarian appeals. Other examples of asserted majoritarianism include Richard Nixon’s “Silent Majority,” for whom he claimed to speak, or Wilmot Robertson’s book *The Dispossessed Majority* (1972). Robertson’s is perhaps the most extreme and tendentious version of majoritarianism in the U.S. context, with its concern for the separation of ethnic groups because of the impossibility of true assimilation.

Though majority rule is not the same as majoritarianism, they are closely related. There are a variety of formal results regarding the potential for purely majoritarian institutions to produce just outcomes. On the negative side, Kenneth Arrow (1963) generalized the Marquis de Condorcet’s finding, rediscovered by Duncan Black

**MAJORITARIANISM**

Majoritarianism is a stark philosophical position defended explicitly by nearly no one but which many debates invoke rhetorically. Majoritarianism is more fundamental than majority rule, which is simply one of many possible political decision rules. Any democratic system obliges the government to respond to the desires of citizens. Any republican system requires that the people understand their obligations to each other and to the larger nation. Majority rule bridges the gap between the two systems of obligation in a particular way. Leaders and policies are selected by majority rule, and citizens have a duty of participation to ensure that choices are not made by minority factions of the population.

Majoritarianism, by contrast, if it were to be implemented fully, would require something closer to what Plato has Thracymachus tell us in *The Republic*: “Justice is the interest of the strongest.” Any policy that thwarts or frustrates “the majority,” by this notion, is inherently and intrinsically undemocratic and destroys the moral fiber of the nation.

In policy debates majoritarianism is most commonly invoked as a counterclaim to arguments for increased diversity or multicultural policies. The claims take the form of an identification of what “we,” the majority, stand for: “we are a Christian nation” or “we are an English-speaking nation” are common majoritarian appeals. Other examples of asserted majoritarianism include Richard Nixon’s “Silent Majority,” for whom he claimed to speak, or Wilmot Robertson’s book *The Dispossessed Majority* (1972). Robertson’s is perhaps the most extreme and tendentious version of majoritarianism in the U.S. context, with its concern for the separation of ethnic groups because of the impossibility of true assimilation.

Plato has Thracymachus tell us in *The Republic*: “Justice is...”
(1958), that purely majoritarian choice will generally produce results that are either arbitrary (indeterminate) or imposed (dictatorial, so control of the agenda is tantamount to choosing the outcome). On the positive side, May’s Theorem demonstrates that even simple majority rule has several desirable properties and can avoid the chaos of Arrow’s result when there are only two alternatives.

Many political theorists point to John Rawls’s *Political Liberalism* as the most important counterpoint to a philosophical majoritarian perspective. Rawls argues that no one conception of identity should dominate and so no one majority can be said have primacy. Instead, Rawls advances a conception of “overlapping consensus,” with each individual committed to fair and respectful treatment of citizens who hold different conceptions of the good, whether it be political or religious.

MAJORITIES

Majorities are defined as proportions larger than 50 percent of the total. This concept is fundamental to the theory and practice of democracy because of the democratic principle of equal human worth. The moral equality of people suggests that deference often should be given to the opinions of the majority when political conflicts require a collective resolution.

BENEFITS AND ATTRACTIVENESS OF MAJORITIES

Several rationales can be used to justify this partiality toward majorities (Dahl 1989). First, it maximizes self-determination by allowing more people to live under conditions they prefer. Second, it maximizes average utility by benefiting the largest number of individuals. Third, it is likely to produce beneficial decisions because people are well informed.

Majorities commonly are treated with special consideration in many areas of the democratic political process. They exert their strongest influence on decision-making activities. Majorities usually have primary control over decision-making institutions and are generally in a position to dictate outcomes. Consequently, forming and maintaining majorities is an important feature of democratic politics.

The attractiveness of majorities for democratic decision making was demonstrated formally in 1952 by Kenneth May, who showed that in choosing between two alternatives, only majority rule satisfies four reasonable conditions for a democratic process: It produces outcomes that are decisive, anonymous, neutral, and positively responsive.

MULTIPLE ALTERNATIVES AND MINORITY INFLUENCE

When the choice set includes more than two alternatives, there may not be a naturally occurring majority winner. In these situations voting procedures can be used that still reflect the basic principles of majority rule. A runoff system, for example, involves a two-stage election. It begins with a preliminary election. If there is no majority winner, the two candidates with the highest vote totals advance to a head-to-head runoff in which majority rule can be used.

An amendment procedure, which often is used in legislatures, also uses majority rule to choose among more than two alternatives. A winner is chosen through a series of pairwise votes decided by majority rule. At each stage the winning alternative advances to face a different competing option.

Variations of majority rule such as unanimity and supermajorities empower minorities in certain situations. The unanimity rule, which requires unanimous consent, effectively gives veto power to any individual voter. A supermajority rule, which requires a proportion greater than a simple majority, also leaves open the possibility of minority control over the outcome of a decision. Similarly, with the plurality rule a winner is chosen on the basis of receiving the largest proportion of votes. In this case an alternative can win with less than a majority.

TWO-PARTY AND MULTIPARTY SYSTEMS

The importance of the use of majorities for exerting political power in a democracy makes it a significant concern
for political actors. Political institutions and conditions, however, can affect the way political power is pursued. Two-party political systems, for example, provide unique strategic environments for parties, candidates, and voters. Competing parties and candidates have an incentive to make their platforms more appealing to centrist voters to maximize their vote totals (Downs 1957). Consequently, voters typically are presented with two relatively moderate alternatives. People who support third-party or independent candidates have an incentive to cast ballots strategically for one of the two major parties to avoid “wasting” their votes.

In contrast, multiparty systems often require the formation of coalitions among competing political parties to establish ruling majorities. Consequently, parties and candidates can achieve political power without having broad-based support. They can concentrate their platforms to appeal to more narrow constituencies that are large enough to secure political representation. Once seated, they can negotiate with others to create a majority coalition. Therefore, voters in a multiparty system often have a wider range of alternatives from which to choose and less motivation to vote strategically.

TYRANNY OF THE MAJORITY

Although majorities have certain normative advantages related to the principle of equal moral worth, they also present dangers in the form of majority tyranny. Political power in the hands of the majority leaves minorities susceptible to harm or exploitation. The criticism of democracy as a form of mob rule reflects the suspicion that an unconstrained majority will misuse its power.

The problem of majority tyranny often is addressed through political institutions in which majority rule is balanced with the protection of minorities. In the *Federalist Papers* the abuse perpetrated by majority factions is identified as a primary obstacle to political justice and the well-being of the American state. Consequently, certain institutional structures and principles were included in the American Constitution and the Bill of Rights, including federalism, the division of powers, checks and balances, and the freedoms enumerated in the First Amendment.

Majorities in a democracy can have an oppressive effect on private individuals in civil society. Alexis de Tocqueville observed that the thoughts and opinions of individuals in a democracy are susceptible to majority tyranny: “[A majority] uses no persuasion to forward its beliefs, but by some mighty pressure of the mind of all upon the intelligence of each it imposes its ideas and makes them penetrate men’s very souls” (Tocqueville 2000, p. 435). This power over public opinion is due in part to the influence of the principle of equality. When individuals are considered equal, there is an inclination to view the greater number in a majority as providing evidence of superior thought. There is also a propensity for individuals to be ostracized socially when they publicly disagree with the majority opinion. These tendencies can make a democratic society vulnerable to uniformity of thought and a dearth of new ideas.

The concept of majorities plays a critical role in democratic thought and practice similar to that of freedom and equality. It provides a general standard for structuring democratic decision making. It also influences the behavior of political actors, who must keep in mind the political advantages of being in the majority. The power that democracies give majorities may be justified normatively. However, it should be viewed with caution. The power majorities have to exert control over the political process allows them to sacrifice the interests of minorities.

MAJORITY RULE

The principle of majority rule in elections and decision-making was introduced in medieval Germanic law and canon law as a consequence of failures to make decisions by unanimity. In fact, in any community, the formation of two or more factions or parties may lead to procedures requiring the counting of votes and the achievement of a majority threshold.

The majority principle has been praised for being the only system that satisfies the following criteria: (1) decisiveness, but only when there are no more than two alternatives (e.g., candidates, parties, or policy proposals) to choose from; (2) anonymity or voter equality; (3) neutrality with respect to issues, so the status quo or the largest
group does not have an advantage; and (4) monotonicity, or a positive response to changes in voter preference.

If there are only two alternatives along a single issue or ideological dimension, such as the left-right axis, majority rule tends to give the victory to the alternative closer to the median voter’s preference. By definition, the median voter—that is, the voter whose preference is located in an intermediate position with less than half of voters on each of the two sides—is always necessary to form a consistent majority in a single dimension. Since the median voter’s preference minimizes the sum of the distances from all other individual preferences, the winner by majority rule in a two-alternative contest minimizes aggregate distance and thus maximizes social utility.

However, this model relies on two strong assumptions: a single-dimensional issue space and only two alternatives. If the set of issues submitted to a majority decision is not bound, the introduction of new issues creating a multidimensional space can change the winner. In a multidimensional space, an alternative—such as a party or candidate’s platform that includes a “package” of proposals on several issues—can make the majority winner unpredictable, depending on which issue takes higher salience in voter choice. In the long term, there can be a series of successive winners relying on different salient issues, with no foreseeable “trajectory.”

When there are more than two alternatives, even in a single-dimensional space, majority rule can be indecisive and unable to produce a winner. Several procedures loosely related to the majority principle can then be adopted. With plurality or relative majority rule, the winner is the alternative that obtains a higher number of votes than any other alternative while not requiring a particular proportion of votes, a result that may imply minority support. Plurality rule has traditionally been used for political elections in the United Kingdom and in former British colonies, including the United States, Canada, and India. Majority runoff requires an absolute majority of votes in the first round of voting, while in a second round the choice can be reduced to the two candidates receiving the highest number of votes in the first round, so as to secure majority support for the winner. Such a system is used for presidential elections in France and in some other countries, including many in Latin America. A majority-preferential vote also requires an absolute majority of voters’ first preferences, while successive counts of further preferences are made to find a candidate with majority support. This system is used in Australia.

With both plurality and majority-runoff or majority-preferential voting, the median voter’s preference can be defeated or eliminated in the first or successive rounds. This implies that the nonmedian winner by any of these procedures might be defeated by another candidate by absolute majority if the choice between the two were available. Extreme minority candidates who are broadly rejected by citizens can paradoxically win by these procedures, based on the majority principle. Majority rule is, thus, dependent on irrelevant alternatives; it encourages strategies aimed at altering the number of alternatives, such as divide and win and merge and win, as well as nonsincere or strategic votes in favor of a less-preferred but more-likely-to-win alternative.

Even when majority rule is decisive and maximizes social utility, as in a single-dimensional space with only two alternatives, it can produce a tyranny of the majority, where one group always wins and there is a permanent losing minority. There has been a long history of concern with the perils of the tyranny of the majority for good democratic governance. Remedies include constitutional guarantees on individual and minority rights, judicial review of decisions made by a majority, mechanisms requiring supermajorities and consensual decisions, and separate elections for different issues, as can be provided by institutional frames of division of powers and decentralization. With separate elections, different majorities and minorities may emerge on different issues, thus creating a broad distribution of political satisfaction or social utility.

If a permanent minority subsists, it may try to secede and establish its own independent democratic system. A previous minority within a large country would then become a local majority and increase the total number of citizens identified with collective decisions and social utility. However, a consistently outvoted minority may not be able to secede because it lacks the military capability to do so or would have to accept resource-poor land or territory.

The major alternative to the principle of majority rule is proportional representation. This system implies representative government, that is, decision-making in two stages: election by voters and decisions made by elected representatives. If the two stages are decided by majority rule, the winner is “a majority of the majority, who may be, and often are, but a minority of the whole” (Mill 1861, chap. 7). In contrast, if the voters’ election is held with proportional representation and the elected representatives make decisions by majority rule, typically by forming multiparty legislative and cabinet coalitions, the system will generally produce a close fit between electoral and legislative majorities. Nonmajority principles are, thus, necessary to guarantee majority government.

MAJORITY VOTING

In the majority voting system, voters cast their ballots for their preferred candidate and the winner of the election is the candidate who receives a majority of the votes, which is 50 percent plus one vote. When there are only two candidates in an election, majority voting is an attractive voting scheme. With more than two candidates, complications may arise.

Social choice theorist Kenneth Arrow, writing in 1951, lists some simple features of a fair and just voting system, and majority voting meets most of his criteria. Majority voting is what Arrow calls monotonic, or responsive. This means, simply, that one voter cannot cause candidate A to win by changing her vote from supporting candidate A to supporting candidate B. This may seem obvious: if candidate A loses support, that candidate ought to be less, not more, likely to win. Yet in many voting schemes this is not the case. Majority voting with runoff elections, a very popular voting scheme, violates monotonicity. This would occur in a three-candidate election, when candidate A could win a runoff election against candidate B alone, but not candidate C alone. Suppose A and C get the most votes, so move on to the runoff, where A loses. But now suppose a set of voters changes their votes from A to B in the first round of the runoff election, and that this means A and B now face off in the runoff. Despite having lost votes, A now wins the election. Arrow further specified that a fair and just voting system must count all votes equally, which majority voting does. No one voter is a dictator, and no group of voters gets more power than any other group. Similarly, majority voting is not biased toward any of the possible outcomes. For example, some systems name the status quo the winner in the event of a tie, thus introducing a bias for the status quo.

Majority voting has attractions beyond the properties Arrow points out. It is simple for voters. All they must do is select one preferred candidate, and they need do so only once. Provided there are only two candidates and an odd-numbered electorate, majority voting always results in elections with clear winners. By definition, one of the two candidates must get a majority of the votes cast. In elections with more than two candidates, majority vote winners accurately reflect the aggregate preferences of the group. If most voters prefer one candidate over all other candidates, that candidate wins. More techni-
tions is thus dubious and that government ought, therefore, to be as limited as possible.

**MALCOLM X**

1925–1965

Malcolm X, a Muslim minister and Black Nationalist leader, was the most formidable race critic in American history. More effectively than anyone before or since, he exposed the moral and legal hypocrisy of American democracy and the ethical contradictions of white Christianity.

Malcolm Little was born in Omaha, Nebraska, to a Baptist preacher and a West Indian immigrant, both of whom were followers of Marcus Garvey (1887–1940), an early proponent of Black Nationalism. Malcolm's first introduction to white supremacy came in infancy, when the Ku Klux Klan drove his family out of town. The harassment continued in Lansing, Michigan, where the Little home was destroyed by arson, and where Malcolm's father was allegedly murdered by another white hate group. His mother had a nervous breakdown and had to be institutionalized, and her six children became wards of the state. After stints in various foster homes, Malcolm dropped out of school and landed in a juvenile detention facility. In his teens, he made his way first to Boston and then to New York, where as “Detroit Red” he became a fixture of the underworld. He dabbled in drugs, prostitution, numbers running, and armed robbery, and was arrested and convicted of the latter a few months shy of his twenty-first birthday.

While incarcerated, he experienced two major conversions. The first was intellectual: realizing that lack of education was a major contributing factor to black oppression, he set himself to read everything he could get his hands on. The second was religious: he became a follower of Elijah Muhammad’s (1897–1975) Nation of Islam, a sui generis American religious sect that embraces the trappings of orthodox Islam while propagating a mythology and inverting white supremacist ideology to proclaim black supremacy instead. The Nation of Islam flourishes in prisons in particular, where its strict code of personal discipline helps many former substance abusers to become clean. It was at this time that Malcolm, in keeping with the Nation's custom, dropped his last name, bequeathed him by slave owners, and took an X in its place, to mark his lost African ancestry. Upon Malcolm's release in 1952, his brilliance, dedication, and charisma, along with the debating skills he had honed in prison, brought him to the highest ranks of the Nation's leadership. He became its national spokesperson, second only to Elijah Muhammad himself, and was appointed minister-in-charge of the prestigious Temple Number Seven in Harlem.

Malcolm X quickly distinguished himself as the most feared, controversial, and articulate race critic in the United States. Since the overt racist violence of southern conservatives was obvious, and was effectively exposed in the media by the Reverend Martin Luther King Jr. (1929–1968) and the civil rights movement, Malcolm focused his critique on the covert racist violence of northern liberals. His attack on these liberals was brutal and persistent. He exposed the responsibility they bore for the creation of the black ghetto, with its poverty, drugs, crime, unemployment, bad schools, and bad housing. While King praised white liberals for their support of the civil rights movement, Malcolm castigated them for their hypocrisy in opposing legal segregation in the South while maintaining de facto segregation in the North.

Although he was often accused of preaching hate and violence, Malcolm simply exposed what was already there. White America had always been hateful and violent toward blacks: 244 years of slavery had been followed by 100 years of segregation. Black America had tried and failed to “overcome” using the principles of love and non-violence. Now it was time for righteous anger and “non-violence.” In other words, blacks needed to start defending themselves and their freedom, just as whites had always done. Only in this way could they affirm their humanity. Malcolm is often contrasted with King, and the latter, a frequent target of Malcolm's sharp tongue, kept a wary distance from him, but by the end of their lives each was moving closer to the other's position. King had become much more radical, and Malcolm much more universal in outlook.
In 1964 Malcolm X broke with Elijah Muhammad and converted to Sunni Islam, taking many of his followers with him. The year that followed marked the first time in Malcolm’s career that he was free to think and speak for himself. It was a period of intense change and creativity, during which he abandoned the racist ideology of the Nation of Islam and tentatively began to reach out to whites and to the mainstream civil rights movement. After a pilgrimage to Mecca, Saudi Arabia, he took the name El-Hajj Malik El-Shabazz, and founded the Muslim Mosque Inc. and the Organization of Afro-American Unity—a religious and a political organization, respectively. He traveled widely, visiting countries in the Middle East, Africa, and Europe, explaining the black struggle for justice in the United States and linking it with other liberation struggles throughout the world. He also collaborated with the writer Alex Haley (1921–1992) on an autobiography. On February 21, 1965, Malcolm X was assassinated at the Audubon Ballroom in New York City, in front of a large crowd that included his wife and children. Three men connected with the Nation of Islam were convicted of the crime; it was widely suspected, though never proven, that Elijah Muhammad himself ordered the assassination.

There are many questions that arise out of Malcolm X’s account of his life as told to Haley, especially the circumstances of his father’s death, the timing of his conversion to Sunni Islam, who set fire to Malcolm’s home, and Malcolm’s sexual orientation. No one has raised these questions as sharply and as controversially as Bruce Perry in Malcolm: The Life of a Man Who Changed Black America (1991). Though his biography received much attention when published, it had little impact on the thinking about Malcolm X among most scholars, largely because Perry’s sources have proven difficult to check.

In 1992 the Spike Lee film Malcolm X made The Autobiography of Malcolm X (1965) a best seller, and sparked a renewal of interest in Malcolm. In the early twenty-first century, he was more popular than ever in the African American community, especially among the young. His name, words, and face adorn T-shirts, buttons, and the covers of rap albums. His writings, books about him, and tapes of his speeches are sold by street vendors, at cultural festivals, and in bookstores. His two most significant speeches, “Message to the Grass Roots” and “The Ballot or the Bullet,” were delivered in the last year of his life—one immediately before his break with the Nation of Islam, and the other soon after. In both of these speeches, he pushed the basic theme that he had sounded from the beginning of his career: black pride. It was by far his most influential notion, yielding Black Power, Black Theology, African American studies, and much else. This cultural philosophy was his last bequest to his people, whom he loved so deeply and for whom he died.

### Malinchistas

The term malinchistas is used by Mexicans and Mexican-origin populations in the United States to refer to community members who “sell out,” adopt the value system of the dominant culture, and implicitly accept the terms of their own subordination. These persons seek to prove themselves as exceptions and embody traits associated with the dominant culture, while they shun those associated with their own. Malinchismo may be defined broadly as the pursuit of the novel and foreign, coupled with rejection and betrayal of one’s own culture.

This term is linked to the history and myth of a sixteenth-century indigenous woman named Malinalli Tenepali (Malintzin), popularly known as La Malinche or Doña Marina (c. 1502–1527). One of the most legendary figures involved in the conquest of Mexico, La Malinche was of Nahua origin and served as interpreter, guide, and concubine to Hernán Cortés (c. 1484–1547). Knowledge about La Malinche’s life before meeting Cortés is derived from the biography that the Spanish soldier Bernal Díaz del Castillo (c. 1495–1584) provides when he recounts La Malinche’s reunion in 1524 with her mother and half brother in his La historia verdadera de la conquista de la Nueva España (The True History of the Conquest of New Spain, written in 1568, published in 1632). Díaz del Castillo states that La Malinche was a born a Nahua to royal indigenous parents in Tenochtitlán, experienced the death of her father and the remarriage of her mother, and was banished by her mother and enslaved to the Chontal Maya from the coastal area of Tabasco, whose cacique, in turn, gave her to Cortés, along with other virgins for sexual and domestic services, as a welcoming gift. She
became Cortés’s lover, gave birth to two mestizo sons, and served as an intermediary and translator between Cortés and Moctezuma (c. 1466–1520). She later married a Spanish soldier named Juan Jaramillo, and gave birth to a forgotten mestiza daughter. She died in 1527 at the age of twenty-five.

Many historians consider La Malinche’s participation as crucial in enabling Cortés to defeat Moctezuma and topple the Aztec Empire in 1521. La Malinche’s abilities in her native Nahuatl and her proficiency in Yucatán dialects proved indispensable to Cortés. La Malinche spoke both Nahuatl (her mother tongue) and other dialects of the Yucatán Peninsula, and, most importantly, she knew the conventions of a register of Nahuatl tecpilatolli (lordly speech), a difficult and indirect rhetorical style used among the Nahuatl-speaking elite. With these special skills, she was able to negotiate successfully for Cortés and counsel him about the intentions of the people with whom he was dealing.

The concept of malinchismo emerged in post-independence nineteenth-century Mexican nationalist historiography and literature. After her representations in Spanish and indigenous sources as a powerful woman commanding respect (for example, Spanish Christian interpretations tend to redeem Doña Marina through accounts of her heroism, religious conversion, and cultural assimilation), Mexicans began to condemn her treacherous role in the conquest of Mexico and focused on her sexuality. The depiction of La Malinche’s “willful betrayal” centers on the events leading to the Spanish massacre of the people of Cholula prior to the Spanish occupation of Tenochtitlán in 1519. According to Francisco López de Gómara (c. 1511–1566) in his Historia de México (1552) and Bernal Díaz del Castillo in the Historia verdadera, La Malinche was given the opportunity to leave Cortés’s service for the protection of the Cholulans, even to the point of entering into marriage with a Cholulan nobleman, but she chose instead to inform Cortés of the Cholulans’ plans to ambush the Spaniards. Her role in interrogating Cuauhtémoc (c. 1496–1525), the last ruler of the Aztecs, during his imprisonment and in interpreting his confession prior to execution during Cortés’s expedition to Honduras is considered confirmation of her treachery. The acts have been considered acts of free and reprehensible choice. An analogue of La Malinche in African American culture is Uncle Tom from Harriet Beecher Stowe’s 1852 antislavery novel, Uncle Tom’s Cabin. Just as La Malinche has been stereotyped as an indigenous woman that sells out her people to the Spanish conquistadors, Uncle Tom has become the stereotype for an African American who is too eager to please whites. Both La Malinche and Uncle Tom “betray” their respective community of origin.

Numerous nineteenth-century Mexican novels depict La Malinche as Eve, the woman to blame for the fall of the Aztec Empire; the child doomed by birth prophecy; the indigenous woman desiring the white man; the ambitious schemer using men for her own egotistical ends; the whore; and the scapegoat for centuries of Spanish colonization. In the twentieth century, Octavio Paz’s (1914–1998) essay “Los hijos de la chingada” (Sons of the Violated One) from his collection El laberinto de la soledad (The Labyrinth of Solitude, 1950) depicts La Malinche as “la chingada” (the violated one), lover, and mistress. La Malinche’s redemption lies in her role as the mother of the first mestizos, though Mexicans remain alienated from their past and suffer as hijos de la chingada. In short, malinchismo portrays indigenous Mexicans as victims of Spanish aggression facilitated by Malinche’s lasciviousness and treachery.

The notion of malinchismo is profoundly misogynistic. The elements of malinchismo were set in the twentieth century: La Malinche is perceived as cursed at birth, driven by an unbridled sexual appetite, unprincipled in pursuit of her own ends regardless of the incalculable price that others must pay for her actions, and culpable for bloody deeds carried out by Cortés and his soldiers.

La Malinche entered into the United States cultural lexicon under the influence of the Chicano movement of the 1960s and 1970s. During this period, Chicano (male) nationalists labeled Chicana feminists and Chicana lesbians as malinchistas. Chicana feminist and lesbian writer Cherríe Moraga engages these negative depictions in her essay “A Long Line of Vendidas” in the collection Loving in the War Years: Lo que nunca pasó por tus labios (What Never Passed Her Lips, 1983). Chicano playwright and screenwriter Luis Valdés in his play Los vendidos (1967) labeled vendidos (sell-outs) or malinchistas those working-class Chicanos and Chicanas who become middle-class Mexican Americans closely aligned with mainstream, middle-class U.S. Anglo cultural values, while they deny their own Mexican working-class heritage. In the late 1970s and early 1980s, Moraga and other Chicana cultural critics and literary writers, however, began to recast the icon of La Malinche as a positive role model for women. They have sought to convert La Malinche into a woman of empowerment and to provide new liberatory potential for the myth. While La Malinche appears frequently as a traitor and scapegoat from the male point of view, feminists in the late twentieth century reclaimed her tale as that of a woman who played a central role in the Western Hemisphere’s formation.

**MALINOWSKI, BRONISLAW**

1884–1942

Bronislaw Kaspar Malinowski is one of the most charismatic personalities in the history of anthropology. Malinowski defined long-term ethnographic fieldwork as the hallmark of social anthropology. His functionalist approach dominated British social anthropology well into the 1950s. He was a powerful promoter of social anthropology as an academic discipline, both by teaching a whole generation of students and by securing research grants through appeal to the usefulness of ethnographic knowledge to projects of development. A European intellectual with wide-ranging interests, Malinowski was gifted at learning languages and was a brilliant writer. Much of today’s fascination with Malinowski revolves around the circumstances of his pioneering fieldwork in Melanesia from 1914 to 1918: how he happened to choose his field sites; how he positioned himself toward the “natives,” colonial administrators, and academic colleagues; how important the method of participant observation was in relation to other data collection techniques; and how different ethnographic experiences were expressed in different forms of writing.

Born in Krakow, Malinowski first studied physics and philosophy, receiving a doctorate from Jagiellonian University in 1908. His readings during this time were broad, with Friedrich Nietzsche (1844–1900) and the physicist-philosopher Ernst Mach (1838–1916) among his intellectual influences (Early Writings [1993]). He spent a further year at Leipzig University studying Völkerpsychologie (cultural psychology) with Wilhelm Wundt (1832–1920). In 1910 Malinowski traveled to Britain and started to study ethnology with Edward Westermarck (1862–1939) and Charles Gabriel Seligman (1873–1940) at the London School of Economics. He was to remain attached to the London School of Economics for most of his academic career, becoming a reader in 1923 and a professor in 1927. Just before the outbreak of World War II (1939–1945), Malinowski was on sabbatical in the United States and decided not to return to Europe. He became a professor of anthropology at Yale University in 1942, but died the same year.

Malinowski’s writings cover a range of different regions (Australia, Melanesia, Mexico), but his most famous works are ethnographic studies of the Trobriand Islands in the southwest Pacific. In Argonauts of the Western Pacific (1922), Malinowski describes the kula, a system of ceremonial exchanges between a group of islands. In Malinowski’s view, the kula is primarily about establishing reciprocal ties, whereas economic gain is only of secondary importance. Magic, religion, and myth are central themes in many of his works. For example, in Coral Gardens

**Mark A. Hernández**
(1935), Malinowski analyzes the function of magic spells in Trobriand horticulture. This work also presents most clearly the powers of Malinowski’s linguistic approach. Crime and Custom (1926) is a pioneering work in legal anthropology. Showing that a society’s ideals about proper conduct must be clearly distinguished from everyday reality, Malinowski carves out a distinctly anthropological perspective on law and society. A number of his works are concerned with Trobriand sexuality and family relations (e.g., Sex and Repression [1927]) and reflect Malinowski’s enduring interest in Sigmund Freud’s (1856–1939) psychoanalytic theories. His more theoretical works, such as A Scientific Theory of Culture (1944), have not preserved the same appeal as his ethnographies. Some of his wartime writings are devoted to a passionate defense of liberalism (Freedom and Civilization [1944]). His posthumously published fieldwork diary (1967) remains controversial because of racist remarks, but has also significantly deepened the understanding of his ethnographic oeuvre.

MALNUTRITION
Malnutrition describes the measurable impairment to individual health and well-being resulting from insufficient or unbalanced food intake relative to physiological needs. The term is often compared and contrasted with hunger, which refers to the subjective feeling of discomfort caused by lack of food, and food insecurity, which describes lack of access to nutritionally adequate food in a socially acceptable manner. Malnutrition usually arises in situations of national or regional food shortage (its acute form is famine), where geographic regions or nations lack adequate food supply, and food poverty, where households lack resources (entitlements) to produce or acquire adequate nourishment. But individual food deprivation also occurs when national and household availabilities are inadequate but distribution is inequitable; in famine situations, some always eat well. World hunger is a composite term covering insufficient availability, access, and utilization of food at global, national, household, and individual levels.

The United Nations Food and Agricultural Organization (FAO) and the World Bank, working from national food production and trade statistics along with household income figures relative to the price of a minimum food basket, estimate that some 800 million people in developing countries are food insecure. This is despite aggregate increases in agricultural production and improvements in market infrastructure that, since the 1970s, have made it technically possible to feed everyone a nutritionally adequate basic diet. The largest proportions of food-secure households and undernourished children exist in South Asia, where endemic poverty is high; numbers are growing also in sub-Saharan Africa, where political instability and HIV-AIDS interfere with food production, marketing, income generation, and intergenerational care.

Within households, pregnant and lactating women, adolescent girls, infants and young (especially weaning-aged) children, and elders are particularly vulnerable to malnutrition where they suffer intrahousehold discrimination in access to food and care relative to their nutritional needs. This vulnerability is further elevated by excessive workloads, infections, malabsorption syndromes, environmental contamination, and insufficient health services. Public health nutritionists study nutrition over the life cycle, beginning with gestational nutrition and breast-feeding, to identify these culturally specific age- and gender-related patterns of malnourishment and to institute more effective food and nutrition policies and practices.

Undernutrition includes both protein-energy (protein-calorie) malnutrition and specific micronutrient deficiencies. Manifestations include growth failure in children, underweight and weight loss in adults, extra burdens of disease, and functional impairments to physical activity, work performance, cognitive abilities, reproductive outcomes, and social life. From the 1930s through the
late 1960s, nutritionists working with the FAO, the World Health Organization (WHO), and the United Nations University (UNU) made prevention of protein deficiency (the “protein gap”) the priority for interventions. In the 1970s emphasis shifted to energy (calories) on the reasoning that if nutritionally deprived children (or adults) could get sufficient quantities of their traditional balanced diet, protein would take care of itself. Increasing food energy also fit the agricultural-intensification agenda of the green revolution that was producing piles of rice, wheat, and to a lesser extent maize in Asia and Latin America but reducing protein-balanced cereal-legume crop mixes. Malnutrition, conceptualized as a factor in longer-term national economic growth and development, also became part of integrated national nutrition and rural development strategies. These strategies were promoted by the World Bank and other foreign-assistance agencies, which launched national maternal-child health and school feeding programs, targeted food subsidies, agricultural diversification and marketing programs as well as income generation and nutrition and health education efforts. Basic needs investments in education, health, clean water, and sanitation tried to address poverty alleviation and malnutrition together while contributing to longer-term economic growth.

In the late 1980s and early 1990s priorities and framing shifted yet again, this time to ending “hidden hunger.” With UNICEF taking the lead, the World Summit for Children (WSC) in 1990 set goals to reduce—by half—mild to moderate energy-protein malnutrition, which had been implicated in more than half of child deaths in the developing world, and virtual elimination of vitamin A, iodine, and iron deficiencies as public health problems. By this time dietary diversification had practically eliminated beriberi (thiamin deficiency, associated with polished rice diets), pellagra (niacin deficiency, associated with maize), kwashiorkor (protein deficiency, associated with dependency on a starchy tuber or sap), rickets (associated with too little vitamin D and exposure to sunlight), and scurvy (vitamin C deficiency). The WSC initiatives combined nutrient supplementation, food fortification, and food-based strategies as strategies to end vitamin A deficiency blindness and impaired immune response, cretinism and goiter (associated with severe gestational and later deficiencies of iodine), and severe iron deficiency anemias. At the same time the WSC’s goal was to correct more moderate deficiencies, which researchers showed could depress physical and intellectual development, work performance, and child survival.

Subsequently the World Food Summit (1996) and the Millennium Development Goals set additional targets and action plans for reducing world hunger numbers and proportions by half, along with their causes, by 2015. In follow-up, nongovernmental organizations (NGOs) and community-based organizations, collaborating with governments and international agencies, increasingly frame approaches in terms of livelihood security (income generation, microcredit, female education) and rights-based development or the right to adequate food (emphasizing government accountability and public-private-community partnerships and participation). NGOs also play a growing role in humanitarian assistance, including the SPHERE project, which disseminates principles, minimum technical standards, and best practices for responding to disasters. Although international famine early warning systems—and attendant obligations for food aid response—have eliminated most severe malnutrition apart from areas of political instability, active conflict, or oppression, seasonal and chronic malnutrition persist where people lack access to markets and government or international assistance and among those experiencing the immediate economic displacements of globalization. Local and global studies analyzing these contexts of malnutrition suggest that to reduce malnutrition and poverty everywhere, it is necessary to overcome the economic, political, and social exclusion of women by improving women’s education, entitlements, livelihoods, and empowerment, especially across South Asia, and providing fairer access to land, water, infrastructure, and terms of trade.

Although conventionally through the 1980s malnutrition usually referred to undernutrition, caused primarily by poverty and improper diet, there has since been increased attention to overweight, obesity, and nutritional “diseases of civilization,” including diabetes, coronary heart disease, and certain cancers associated with unhealthy diets and behaviors. These syndromes are on the rise also in developing countries, which are experiencing dietary transitions away from traditional, balanced local diets based on grains, legumes, oilseeds, and small amounts of animal protein plus fruits and vegetables toward modern, unbalanced, global diets characterized by more processed and “fast” foods that are higher in fats and simple sugars. Nutritionists studying the etiology of malnutrition now find overweight and underweight individuals residing in the same households, as both low- and higher-income people fill up on cheaper, calorie-dense snacks and sugary beverages. Genetically modified foods and corporate control over the global food system are additional contentious issues for the present and future.

MALTHUS, THOMAS ROBERT
1766–1834

Malthus is now a word, like Luther or Marx or Darwin, that connotes both much more and much less than the individual to whom it refers. The important social-scientific ideas associated with Malthus are:

1. the inevitability of population pressures in human societies,
2. scarcity as the central principle of economic analysis,
3. “spontaneous order” and the futility of political revolution,
4. Poor Laws and “welfare dependency,”
5. the theory of general unemployment, and
6. the struggle for existence.

Thomas Robert Malthus—always known as “Robert” or “Bob,” never as “Thomas”—was born in Surrey, England, on February 13, 1766, the younger son of Daniel Malthus (1730–1800), a country gentleman. He died in Bath on December 29, 1834, and is buried in Bath Abbey. Educated first privately, then at Warrington Academy and at Jesus College, Cambridge, he graduated BA as Ninth Wrangler in 1788, residing at Cambridge for a further year to read divinity, then was ordained deacon in June 1789 and priest in 1791. Although elected a fellow of his college in 1793, he served a country curacy at Okewood in Surrey from 1789 until 1803, when he became rector of Walesby in Lincolnshire, relinquished his fellowship, and married. In 1805 Malthus was appointed first professor of history and political economy at the East India College, a position he held until his death. He also retained the benefice of Walesby as a nonresident, appointing a curate.

While still curate of Okewood, Malthus wrote the book that made him famous: An Essay on the Principle of Population (1798). Though greatly enlarged in 1803 and appearing in four further editions during his lifetime, the first Essay contains the seeds of all “Malthusian” social-scientific ideas save possibly the theory of general unemployment.

HUMAN POPULATION: THE “RATIOS” AND THE “CHECKS”

The first Essay was written to show the unfeasibility of William Godwin’s Political Justice (1796). Godwin (1756–1836) believed that humans are naturally “benevolent,” and that the moral evil we perceive is caused by social institutions, which should therefore be dismantled. But if Godwin’s “beautiful system of equality” is fully realized, all property equally divided, and marriage, wage labor, government, and law abolished, the economic and social constraints on procreation are removed and population can grow geometrically (exponentially) at first. As fertile land becomes scarce, food needed to support more people cannot be produced at the same rate. Malthus assumes “no limits … to the productions of the earth” (p. 26), but suggests that food can only be made to increase, at the utmost, arithmetically (linearly). Hence per capita income must fall. Long before it reaches the “subsistence” (zero population-growth) level, falling real income reawakens “the mighty law of self-preservation”: Theft and falsehood undermine the mutual trust on which “benevolence” depends; “self-love resumes his wonted empire and lords it triumphant over the world” (p. 190); and the most able and powerful convene to institute “some immediate measures to be taken for general safety” (p. 195). Property rights reappear, together with sanctions for their violation, requiring the restoration of government. Wage labor is reintroduced to ration scarce food to the landless. Marriage comes back to assign responsibility for the feeding and care of children. Godwin’s “beautiful fabric of the imagination vanishes at the severe touch of truth” (p. 189).

Malthus acknowledged that the “principle of population” was not new. That human populations multiply “like mice in a barn” (Cantillon [1755] 2001, p. 37) when unconstrained by resource scarcity was taken for granted by all eighteenth-century social theorists. Malthus’s new wrinkle, occasionally hinted at by his predecessors and recognizably formulated by James Anderson in 1777, was an analysis of the effects of population growth with scarce land. When natural resources are limited, human fecundity makes population pressure inevitable. Rational individuals may and often do respond with some variety of the preventive check: measures to restrict procreation ranging from “moral restraint” (delay of marriage without “irregular gratification,” Malthus’s preferred solution) to contraception, as recommended by “neo-Malthusians” such as the young John Stuart Mill (1806–1873), but which

Ellen Messer
Malthus himself ruled out as un-Christian, and subversive of the work ethic. Failing any or enough of these, the real incomes of some must fall so low that the positive check will operate: Population will be arrested by famine, starvation and disease, high infant mortality, and shortened adult lifespan.

SCARCITY AND DIMINISHING RETURNS

Though the economists Richard Cantillon (1680–1734), François Quesnay (1694–1774), Adam Smith (1723–1790), and others were conscious of land scarcity, they did not integrate the concept into their economic analyses. For Smith, the brake upon economic growth was shortage of capital, not of land. Now a capital shortage can always be remedied by the “parsimony” of capitalists, and hence is not a necessary feature of economic analysis. But land scarcity is given by nature and is permanent.

Successive applications of labor and capital to a given supply of land result in ever-diminishing returns: at the extensive margin as lower-quality land is brought into cultivation; and at the intensive margin as each successive unit of the variable factor (labor-plus-capital) has less of the fixed factor (land) to work with. Between 1798 and 1815 the analytical implications of the first Essay gradually became clear to Malthus himself and to Robert Torrens (1814–1884), Sir Edvard West (1782–1828), and David Ricardo (1772–1823). In the latter year each published papers expounding the so-called “classical” theory of rent: Land is cultivated up to the point at which the diminishing marginal product of labor-plus-capital is equal in value to the competitively determined factor cost; capitalist farmers divide the factor payment into profits and wages; and landlords get a surplus (“rent”) equal to the excess value of intramarginal production over total cost of production.

Two years later Ricardo codified all this in his Principles of Political Economy (1817). Adam Smith’s “cheerful” study of the Wealth of Nations was replaced by a “dismal science” of scarcity, and “classical political economy” was born. Half a century later, economists in England, Austria, Switzerland, and the United States generalized diminishing returns to construct “neoclassical” production theory. All factors are substitutable, and the contribution of each and every factor is subject to diminishing returns when all other inputs are constant. When the production functions implied by this analysis are confronted with isomorphic utility functions, generalized resource scarcity implies the “budget constraints” of the latter, and economic theory becomes an investigation of constrained maximization by rational agents. The present-day view of economics as the study of the allocation of scarce resources between competing ends is a direct consequence of Malthus’s Essay on Population.

“SPONTANEOUS ORDER” AND THE FUTILITY OF POLITICAL REVOLUTION

Edmund Burke’s Reflections on the French Revolution (1790) rested on a view of civilized human societies as dynamically unstable systems. An exogenous dissolution of the social fabric producing anarchy causes society to collapse into a state of “tyranny,” from which it can only be dislodged by successful counterrevolutionary action. Godwin’s answer to Burke accepted the assumption of instability, but supposed that the effect of anarchy is to launch society upon a growth-path of never-ending progress toward the goal of human perfectibility. Malthus’s decisive intervention in the debate undermined both Godwin’s argument and Burke’s. Anarchy may be morally superior to the status quo as Godwin believed. But the “laws of nature” then operate: first to produce a state of affairs inferior to the status quo; and because of this, eventually to restore the system to its original state. Political revolution is therefore costly, futile, and self-reversing.

Malthus’s conception of human societies as dynamically stable systems is a corollary of the theory of “spontaneous order” attributed by F. A. Hayek to Scottish Enlightenment thinkers, in particular David Hume (1711–1776) and Adam Smith, each of whom Malthus had studied with great care. Things get to be the way they are not because anyone intended and planned the present state; rather, the status quo is the unintended consequence of countless private, self-regarding decisions in the past. It is stable in the sense that those now in a position to effect change prefer things as they are, and have strong incentives to restore equilibrium if it is exogenously disturbed.

This conception is of the highest scientific importance, for Burke’s and Godwin’s arguments are equally defective. By postulating instability of the status quo they leave unexplained and inexplicable the way society becomes what it is. Malthus’s stable equilibrium model is not only central to all subsequent economic analysis: It is an essential feature of all present-day attempts to explain social phenomena as the outcome of rational choice by individuals.

THE POOR LAWS AND “WELFARE DEPENDENCY”

In 1798 and in all subsequent recensions of the Essay on Population (1803, 1806, 1807, 1817, 1826), Malthus criticized the Elizabethan Poor Laws then in force in England, first, because they tended to “increase population without increasing the food for its support” (1803, p.
358); and second, because any transfer to the indigent “diminishes the shares that would otherwise belong to the more industrious, and more worthy members” of the working class (1803, p. 358). The “more worthy” are those in whom “a spirit of independence still remains,” and the “poor-laws are strongly calculated to eradicate this spirit” by lowering the cost to individuals of “carelessness, and want of frugality,” and by weakening the incentive to postpone marriage and procreation (1803, p. 359). Because “dependent poverty ought to be held disgraceful,” the poor laws, by removing that stigma, “create the poor which they maintain” (1803, pp. 359, 358). What is now called “welfare dependency” was clearly recognized by Malthus not as moral turpitude among the lower orders but as their rational response to a perverse set of incentives.

The incentives are perverse because it is through the preventive check alone that the working class can obtain higher wages and a larger share of national income. Malthus, following Smith, William Paley (1743–1805), and many others, saw that the “subsistence” wage is a cultural variable. If workers raise their sights and come to expect a higher real income before marrying, the aggregate labor supply will be reduced and the equilibrium real wage increased to match their expectations. In terms of the “classical” theory of rent, factor cost rises and the share of income going to both capitalists and laborers increases at the expense of rents. Welfare dependency, in contrast, reduces both the absolute and the relative income of workers.

THEORY OF GENERAL UNEMPLOYMENT

Like his eighteenth-century predecessors, Malthus saw economic activity as driven by “effectual demand.” His Principles of Political Economy (1820), written partly to criticize Ricardo’s value theory, attempted in chapter 7 to explain the post-1815 depression as a “general glut” in commodity markets. An increase in parsimony by capitalists diverts expenditure from “unproductive” to “productive” labor, thereby increasing the supply of goods while reducing the demand. Therefore, unless landlords and others of “the rich” can increase “unproductive expenditure” (personal services, luxuries, etc.) correspondingly, excess supply will drive down prices and profits, “check for a time further production,” and throw labor out of employment (1820, p. 354).

Ricardo, James Mill (1773–1886), Jean-Baptiste Say (1767–1832), and most other contemporaries rejected the possibility of “general gluts” on the grounds that produced goods must count as expendable income for those who own them, therefore “supply creates its own demand.” Malthus and Ricardo continued the debate in their celebrated correspondence, but Malthus’s formulation was never sufficiently clear to convince the latter, and his theory—shared to some extent by Jean Charles Léonard de Sismondi (1773–1842) and Thomas Chalmers (1780–1847)—was treated by J. S. Mill and most later economists as a regrettable mistake.

John Maynard Keynes (1883–1946), however, was a lifelong admirer of Malthus, whom he called “the first of the Cambridge economists,” and he abetted Piero Sraffa (1898–1983) in his recovery and edition of the Ricardo-Malthus correspondence. When in the early 1930s Keynes was beginning to construct his own quite different theory of demand-led aggregate production and employment he was inspired, if not exactly influenced, by Malthus’s conscientious though flawed attempt to do justice to the whole of economic reality; and he averred that “the almost total obliteration of Malthus’s line of approach and the complete domination of Ricardo’s … has been a disaster to the progress of economics” (Keynes 1972, p. 98).

THE “STRUGGLE FOR EXISTENCE”

In October 1838, shortly after returning from the voyage of the Beagle, Charles Darwin “read for amusement Malthus’s Population, and being well prepared to appreciate the struggle for existence … it struck me that under these circumstances favourable variations would tend to be preserved and unfavourable ones to be destroyed [implied in chapter 3 of the Essay, where the phrase “struggle for existence” occurs]. Here then I had at last got hold of a theory by which to work” (Darwin 1974, p. 71).

Modern biology is “Malthusian” in two analytically distinct ways. In the short run in which all genes may be taken as given, the science of ecology—a study of the general equilibrium of coexisting species in defined space—generalizes Malthus’s partial equilibrium analysis of human populations to explain what J. S. Mill called “the spontaneous order of nature.” In the long run in which there is genetic mutation and adaptation of species, the theory of organic evolution generalizes Scottish Enlightenment “conjunctural history” central to Malthus’s anti-Godwin polemic.

The dominance of scarcity in human affairs is never a welcome message. From the first, Malthus’s work has provoked vigorous controversy, ranging from technical and sometimes cogent objections to details of his arguments by fellow economists to outraged vilification by Romantics, Marxists, Christian Socialists and advocates of the welfare state, few of whom seem to have read what Malthus actually wrote.

MALTHUSIAN TRAP

The Reverend Thomas Robert Malthus was born in Surrey in 1766 and died in 1834. He was the son of a clergyman and one of eight children. Malthus was educated at Jesus College, Cambridge, and later became a professor of history and political economy at the East India Company’s College at Haileybury in Hertfordshire. His most famous work, the Essay on the Principles of Population, was published in 1798 when he was thirty-two. It has been interpreted partly as a reaction to the utopian thought of William Godwin (1756–1836) and others, as well as that of Malthus’s own father. It is an extension and formalization of the work of the classical economist Adam Smith (1723–1790) and others who had laid down some of the basic ideas concerning the tendency of population to outstrip resources.

Malthus’s theory, in brief, was that humankind is permanently trapped by the intersection of two “laws.” The first law concerned the rate at which populations can grow. He took the “passion between the sexes” to be constant, and investigations showed that under conditions of “natural” fertility (with early marriage and no contraception, abortion, or infanticide), this would lead to an average of about fifteen live births per woman. This figure is confirmed by modern demography. Given normal mortality at the time, and taking a less than maximum fertility, this will lead to what Malthus called geometrical growth of one, two, four, eight, sixteen, and so on. Only thirty-two such doublings are needed to lead from one original couple to a world population of over six billion persons.

The second premise was that food and other resource production will grow much more slowly. It might double for a generation or two, but could not keep on doubling within an agrarian economy. Thus there could, in the long run, only be an arithmetical or linear growth of the order of one, two, three, four. Incorporated into this later theory was the law of diminishing marginal returns on the further input of resources, especially labor. Underpinning the scheme was the assumption that there was a finite amount of energy available for humans through the conversion of the sun’s energy by living plants and animals. The conclusion was that humankind was trapped, a particular application in the field of demography of the more general pessimism of Adam Smith. Populations would grow rapidly for a few generations, and then be savagely
cut back. A crisis would occur, manifesting itself in one (or a combination) of what Malthus called the three “positive” checks acting on the death rate: war, famine, and disease.

After the publication of this theoretical account of the “laws” of the trap, Malthus undertook a great deal of empirical research, traveling through Europe and reading widely in history and anthropology. On the basis of this research, he published what is termed the second edition of *The Principles* (1803) but which is, in effect, a very different book. Basically, Malthus turned his laws of population into tendencies, likelihoods, or probabilities, to which there were exceptions. The trap became avoidable, for he had discovered in England itself, as well as in Switzerland and Norway, that there were what he called “preventive checks” that could act to suppress fertility to a level that would be in line with resource growth. He divided these checks into “moral restraint” (celibacy and delayed marriage) and “vice” (contraception of all kinds, abortion, and infanticide), of which he disapproved.

Malthus believed that the only force strong enough to overcome the biological drive to mate was a set of desires created in societies and cultures where people were affluent, unequal, and ambitious for social status, and thus willing to forgo the delights of large families for other goals. A mixture of human avarice and human reason could lead people to avoid the Malthusian trap.

Malthus’s work was hugely influential at the practical level. He contributed to the discussion of the reform of England’s Poor Law and to the ideas of how to run the British Empire, many of whose administrators he taught at the East India Company’s College. He is also the only social scientist who has had a revolutionary effect in the biological sciences. His idea that humans normally suffer from very high mortality rates, that war, famine, and disease periodically cut swathes through historical populations, was seminal. Entirely independently, both Charles Darwin (1809–1882) and Alfred Russel Wallace (1823–1913) described how reading Malthus’s *Principles* provided them with the key to unlock the secret of human evolution, that is, the principle of the survival of the fittest, random variation, and selective retention.

There have been a number of criticisms of the Malthusian framework. His predictions were not fulfilled, at least in the middle term. Malthus wrote before the huge resources of energy locked up in coal and then oil became widely available for human use. For a while, from the middle of the nineteenth century, it looked as if the Malthusian trap was no longer operative. A combination of science (in particular chemistry) and new resources had made it possible to more than double production in each generation. First England, then parts of Europe, Japan, and elsewhere, escaped from the trap. It appeared that Malthus’s laws could be inverted: population grew slowly, resources exponentially.

Ester Boserup (1981) and others have suggested that Malthus mistook cause for effect. It is argued that human ingenuity will find solutions to population pressure and that growth of population is one of the necessary spurs to technical innovation and the development of civilizations. For example, the transformations from tribal to settled peasant civilizations, and then from peasantries to advanced industrial societies, were propelled and made possible by the growth of population.

At a more abstract level, thinkers on the Far Left, such as Chinese Communist leader Mao Zedong (1893–1976), argued that Malthusianism was merely a capitalistic philosophy, and that under communism, populations would automatically stabilize at the right level. This view is inverted and reflected by a number of Catholic writers who argue that since God has planned our lives, and since all forms of contraception are immoral, there is no need to worry about the so-called laws of population. There is no trap.

Others point out that there is no simple correlation between rapid population growth and economic advance. For example, since the mid-twentieth century, India has become richer and less famine-prone as its population has grown, while a number of sparsely populated areas in the Horn of Africa have suffered from the Malthusian trap. So there are clearly many intermediary variables.

Yet it is too early to forget Malthus, as the Chinese decided after a generation of the Communist experiment. In the early twenty-first century, as resources reach their limits and the external costs of the massive use of carbon energy become apparent in pollution and global warming, it appears that the ghost of Malthus has arisen again. Likewise, as we realize the ability of microorganisms to outpace human medicine, our ability to overcome disease in an increasingly crowded world seems at risk. Finally, the tensions that lead to war are further aggravated by shortages and crowding.

Malthus’s realistic message that we can postpone the crises of war, famine, and disease but that they will almost certainly strike again in a much more serious way within an increased total population, again makes sense. His advice, that only by stabilizing and probably reducing total population levels through the rational control of fertility, seems ever more salutary. Like all traps, the Malthusian trap can be avoided. Yet it can only be circumvented if people remain constantly aware of its nature as specified by the lucid first theoretical exponent of the biological limits imposed by human nature and the physical world.

**MANAGEMENT**

Management is a set of functions and tasks performed by individuals and groups for the purpose of enabling an organization to achieve its objectives. From one perspective, management consists of planning, organizing, staffing, directing, and controlling (Koontz and O'Donnell 1982). From another perspective, management is distinguishable from, yet operates in tandem with, leadership, which consists of envisioning, enabling, and energizing functions and tasks (Nadler and Tushman 1990). In short, leaders formulate organizational strategy, set direction, mobilize resources, and motivate people to perform, whereas managers execute organizational strategy by clarifying expected behavior, instituting measurements, and administering rewards and punishments (Kotter 1990).

The distinction between management and leadership is relatively new, largely because for much of the twentieth century the majority of industries in the United States and other nations were characterized by oligopoly (a few firms possess concentrated market power) or monopoly (one firm possesses sole market power). When a firm—an organization—possesses market power, it does not need much in the way of leadership because customers have little or no choice in terms of alternative products or services and because there are few or no rival firms that pose competitive threats. In such circumstances a firm needs only management to ensure that organizational objectives will be met.

Irrespective of the competitive structure of particular industries, traditionally managers and leaders of business (and nonbusiness) enterprises have maximized the objectives of those enterprises. Such maximizing behavior is consistent with the utility maximization principle that underlies both classical and neoclassical microeconomics (Marshall 1923) and with the optimization principle that is at the core of management science (Starr and Miller 1960). But when it comes to management, there is a plethora of concepts, evidence, and experience that indicates that management settles for second- or even third-best when it comes to organizational performance (Simon 1947). An especially influential example in this regard is the work of Frederick W. Taylor (1911), the father of scientific management, who early in the twentieth century showed that management consistently and systematically underperformed. Applying the principles of industrial engineering to the design of work, Taylor demonstrated how most jobs could be reconstructed to enhance productivity with no change in the quantity or mix of factors of production—land, capital, and especially labor. Taylor's work ultimately led to the development and widespread adoption of motion time management (MTM), or time study, whereby jobs were reengineered to maximize efficiency and standard times were set for workers to perform those jobs, with consequent pay rewards if workers overperformed and pay penalties if workers underperformed.

Taylor's conception of management was a single-minded one in which supervisors (and, by inference, managers) did the thinking and issued orders with which workers would presumably comply. But workers proved to be far more independent-minded, even obstreperous, than Taylor envisioned, and they often banded together to attempt to influence and change their terms and conditions of employment. A prime example of this was the industrial union movement of the 1930s, during which workers from a wide variety of companies sought official recognition in order to negotiate collective bargaining agreements with the managements of those companies. That these efforts were strongly resisted by company management is readily evident from historical accounts of labor violence during this period (Rayback 1966).

Ironically, the scientific management movement was followed by, and in significant respects supplanted by, the “human relations” movement, which was founded on the principle that workers are social beings rather than only or even primarily economic beings. The well-known work of Elton Mayo (1933) and his colleagues, which was conducted at the Hawthorne Works of the Bell Telephone System, showed that workers' job performance could be greatly enhanced if management paid close attention to workers' social needs rather than merely to their economic needs (Roethlisberger and Dickson 1939). This research was instrumental to the adoption by many companies of employee counseling and industrial welfare programs aimed at addressing workers' noneconomic needs. Yet at the same time companies strongly and in some cases militantly opposed workers' efforts to form independent unions and bargain collectively with their employers. Responding to these developments during the Great Depression, the U.S. Congress in 1935 passed the landmark National Labor Relations Act (NLRA), establishing...
unionization and collective bargaining as labor policy for the private sector—a policy that was ultimately upheld by the U.S. Supreme Court.

As management thought and practice continued to evolve, more attention was paid to external and internal alignment. External alignment refers to the relationship of an enterprise to its external environment and involves the scanning of economic, political, legal, and social developments, the analysis of competitive opportunities and threats, the positioning of the enterprise in its particular sector or industry, and ultimately the formulation of a business strategy and specification of strategic objectives. Internal alignment refers to the linkages among and balancing of elements such as organization structure, reward systems, decision-making processes, human-capital skills and capabilities, and organization culture, all of which are key to the implementation of business strategy.

Each of these external and internal alignment dimensions is the province of specialized academic research; a leading example is Alfred Chandler’s work on organizational structure. Chandler (1962) postulated that an organization’s structure was fundamentally shaped by the organization’s strategy, which meant (among other things) that there is no one ideal organization structure for all enterprises. Based on this reasoning, a classical functional structure aligned well with certain businesses’ strategies, whereas product-based, geographical-based, and matrix structures aligned well with other businesses’ strategies. From this work there developed a more robust contingency model of organizational structure, and similar contingency models were applied to other elements of internal organizational alignment. The main insight or message of such contingency models is that there is no one best way to operate a business in any of its key dimensions.

As the competitive advantage of business enterprises has come to lie more with human or intellectual assets (capital) than with physical assets (capital), much attention has been devoted to the management of human resources for competitive advantage. In this regard there is considerable empirical evidence that decentralized organizational structures and decision making together with team-based work lead to superior performance compared to hierarchical organization structures, centralized decision making, and individual-based work. In particular the notion that competitive advantage can be achieved through the “high-involvement” management of people has taken hold quite firmly in management circles (Pfeffer 1994); from this perspective, employees are managed as assets. But it is also the case that competitive advantage can be achieved through “low-involvement” management of people, most especially through outsourcing and short-term employment contracting, in which employees are managed as labor expense to be controlled (Lewin 2001).

Both types of human-resource management practices can lead to positive economic returns to a business enterprise.

Finally, much attention has been devoted to the types of incentives systems that best harmonize the interests of business owners and employees, including management employees. The underlying concern, captured by the notion of agency theory, is that management and employees are agents of the principals or owners of a business and as such seek to maximize their own interests rather than those of the principals or owners (Jensen and Meckling 1976). To combat this problem, incentive systems that tie at least some of the pay of managers and employees to the performance of the business have been widely advocated. Such incentives include profit-sharing, bonuses, gain-sharing, productivity-sharing, commissions, stock ownership, and stock-option plans (Lewin and Mitchell 1995). What these plans have in common is that they pay off when a business does well and do not pay off when a business does poorly, which is analogous to what happens to the owners of a business, including shareholders.

MANAGEMENT SCIENCE

Management science is the experimental study and systematic application of a coordinated process for reaching individual and collective goals by working with and through human and nonhuman resources to continually improve value added to the world.

In historical non-Western civilizations, management topics were addressed by Egyptian pharaohs, Chinese mandarins, pre-Hispanic American chiefs, and Arabic scholars like Ibn Khaldun (1332–1406). However, in Western civilization after the Protestant Reformation, worldly prosperity achieved through hard work in this life became a sign of divine approval, and individuals became motivated to exercise self-discipline at work to earn eternal salvation. Adam Smith (1723–1790) provided the economic rationale for free trade and capitalism to increase individual, group, and national wealth—while critiquing the effects of the division of labor. During the Industrial Revolution, the technological development of steam power, railroad transportation, enormous factories, and production changes required new management skills to rapidly handle large flows of material, people, and information over great distances.

Frederick W. Taylor (1856–1915) was the first to develop a science of the management of others’ work for controlled adaptation of labor to the needs of financial capital in his 1911 work, The Principles of Scientific Management. His model was the machine with its cheap, interchangeable parts, each of which does one specific function. Taylor attempted to do to complex organizations what engineers had done to machines, and this involved making individuals into the equivalent of machine parts. Just as machine parts were easily interchangeable, cheap, and passive, so too should the human parts be the same in the machine model of organizations.

This approach involved breaking down each task to its smallest unit to figure out the one best way to do each job. Then the engineer, after analyzing the job, would teach it to the worker and make sure the worker performed only those motions essential to the task. Taylor attempted to control each element of work and to limit human behavioral variability in order to increase productivity.

The results were profound. Productivity under Taylorism went up dramatically. New departments, such as industrial engineering, personnel, and quality control, arose. There was also growth in middle management as there evolved a separation of planning from operations. Rational rules replaced trial and error; management became formalized and effectiveness increased. Henry Ford (1863–1947) successfully applied scientific management processes in the mass production of inexpensive automobiles using the assembly line. He reduced car assembly time from 728 hours to 93 minutes and increased market share by 40 percent.

Of course, scientific management did not come about without criticism. First, the old-line managers resisted the notion that management was a science to be studied, not a status that was conferred at birth or by inheritance or acquired through an intimidating physical presence or force of personality. Second, many workers resisted the dehumanization of their work due to managerial overcontrol of the labor process in a way that ignored workers’ conceptual and craft skills and deprived them of discretionary time-motion options and work design input. The industrial engineer with a clipboard and a stopwatch, standing over workers to control their task motions and work pace, became a hated figure and led to group resistance.

To counter and complement Taylor’s emphasis on external control of labor, three major approaches have developed over the years, focusing on the following managerial emphases: internal flexibility, internal control, and external flexibility.

First, with respect to emphasizing the internal flexibility of managers, the human relations approach, based on the experiments of Fritz J. Roethlisberger (1898–1974) and William J. Dickson (1904–1989) described in Management and the Worker (1939), demonstrated that work is not merely a mechanical, physical act but an expression of multiple psychosocial needs requiring managerial flexibility. When managers give special attention to employees, productivity is likely to improve regardless of whether working conditions improve—the Hawthorne effect. In The Functions of the Executive (1938), Chester I. Barnard (1886–1961) reinforced this view of the organization as a social system requiring employee cooperation and acceptance of workplace authority. Kurt Lewin (1890–1947), in Frontiers in Group Dynamics (1946), further demonstrated that human work systems could not be understood—much less improved—without factoring in
the social-psychological impact of group dynamics in decision making and work performance.

Second, with respect to emphasizing the internal control of managers, Max Weber (1864–1920) maintained that efficient, impersonal coordination of standardized procedures by means of a hierarchy of formal authorities to ensure bureaucratic internal control of labor was the prototypical new role for managers in any organization. Herbert A. Simon (1916–2001) further demonstrated, in The New Science of Management Decision (1960), that the internal organization of firms was the result of decisions made by managers facing uncertainty about the future and costs in acquiring information in the present. Under decision theory, Simon claimed that managers have only “bounded rationality” and are forced to make decisions not by “maximizing” but by “satisficing,” that is, setting an aspiration level that, if achieved, they will be happy enough with. If the aspiration level is not achieved, managers will try to change either their aspiration level or their decision to internally control labor.

Third, with respect to emphasizing external flexibility, Paul Lawrence and Jay Lorsch, in Organization and Environment (1968), maintained that the context of fast-paced uncertainty and global risks required modern managers to creatively adapt and acquire external resources to thrive. They argued that a rapidly changing external environment demanded a dynamic, open-systems approach to management with an organizational feedback structure more like an “ad-hocracy” than a bureaucracy. One of the first contingency theorists, Fred E. Fiedler, in Leader Attitudes and Group Effectiveness (1958), argued that managerial performance depended (was contingent) upon the manager’s match with three situational factors: leader-member relations, task structure, and position power.

In summary, the four major approaches to management compete and complement each other, requiring both control and flexibility to demonstrate managerial excellence.

MANAGERIAL CLASS

The idea of a distinct managerial class with interests that diverge from those of both the capitalist class and the working class is associated with three broad theoretical agendas in the social sciences: (1) the explication of the historical and sociological significance of the rise to power of a layer of intellectuals and state bureaucrats in socialist (communist) countries ostensibly committed to achieving a “classless society”; (2) the analysis of a putative separation of ownership and control within the modern capitalist corporation; and (3) the attempt to delimit and more rigorously define a “middle class” occupying a mediating position between capital and wage labor in advanced capitalist societies. The concept is closely associated with the notion of a rising “new class” of technocrats and intellectuals whose class project is to subordinate modern society to the rules of bureaucratic rationality and the imperatives of science and technology. It is also linked to the idea of a “managerial revolution,” which has rendered obsolete the Marxist theory of the centrality of the capital-labor struggle to the social dynamics of modern or postmodern societies.

Speculation regarding the global ascendancy of a “new” managerial class reached its high point during the early to middle phases of the cold war, finding expression in the thesis that modern, industrialized societies, whether nominally socialist or capitalist, were “converging” toward a unitary (technocratic) model of social and economic organization, one dominated by the requirements of efficiency, productivity, and social responsibility. According to this convergence thesis, the movement of Western capitalist societies toward greater government intervention in the economy and the expansion of the welfare state was no less inexorable than the economic and political liberalization and eventual democratization of the Soviet-bloc
countries. In East and West alike, these processes would be guided by an increasingly self-conscious class of technocrats and intellectuals seeking a middle ground between the freewheeling, individualistic capitalism of a bygone era and the stultifying authoritarianism of “actually-existing socialism.”

The demise of “real socialism” in Eastern Europe and the Soviet Union in the 1990s and the growing influence in the capitalist West of neoliberal policies and ideological nostrums following the profitability crises of the 1970s called into question the continuing theoretical salience of the idea that capitalists and wage workers alike were being eclipsed by a rising new class of “managerial experts.” Indeed, it is arguable that these developments have combined to reduce significantly the influence and relative weight of managerial and technocratic strata in the post-Soviet era, encouraging the revival of a more traditional capitalism, one that “can—and must—manage with a substantially smaller buffer between capital and labour than it did during the more economically prosperous, but also more politically perilous, days of the Cold War” (Smith 1997).

THE MANAGERIAL REVOLUTION
In The Modern Corporation and Private Property (1932), Berle and Means sounded an early alarm concerning the centralization of economic power in the hands of large-scale corporations and the usurpation of power within them by a class of professional managers whom they saw as increasingly unaccountable to shareholders and the general public alike. The immediate impact of this thesis in the crisis-ridden 1930s was to encourage the notion of a “managerial revolution” among many socialist intellectuals disillusioned by the experience of Stalinism in the Soviet Union. This idea found inchoate expression in Lewis Corey’s The Crisis of the Middle Class (1935) and a more fully blown elaboration in Bruno Rizzi’s The Bureaucratization of the World (1939) and especially James Burnham’s The Managerial Revolution (1941). Theorists of a managerial revolution argued that capitalism was in the process of being replaced, not by working-class socialism, as Marx had anticipated, but by a new “collectivist” social formation ruled by a new class of bureaucrats and technocrats.

The Berle-Means thesis of a “separation of ownership from control” was to be given a decidedly positive inflection by many institutional economists and sociologists in the postwar era (notably Talcott Parsons, Neil Smelser, Ralf Dahrendorf, Daniel Bell, and John Kenneth Galbraith) who saw this separation as conducive to an attenuation of conflict between socially irresponsible capitalists and socialist-minded workers, as well as to the triumph of meritocratic, democratic, and technocratic principles over the prerogatives of property ownership.

MARXISM, THE MIDDLE CLASS, AND THE IDEA OF A MANAGERIAL CLASS
The revival of interest in Marxist class theory and socialist politics in the 1960s and 1970s brought to the fore a new set of concerns pertaining to the character and role of the professional, managerial, and other “middle” strata of the advanced capitalist countries. In Europe, in particular, concrete questions of socialist political strategy compelled many left-wing intellectuals to confront the issue of the numerical decline of the industrial working class and the class position of new layers of waged and salaried employees in corporate bureaucracies, service industries, and state apparatuses.

The specifically professional or managerial elements of these new strata were often seen as belonging to a “new middle class.” Reprising in some ways the earlier ideas of Corey and Burnham, Alvin Gouldner (1979) suggested that a “New Class” of technical intelligentsia was arising in the bureaucratic organizations of such societies; but unlike the earlier theorists of “managerial revolution,” he saw this class as in conflict with other bureaucratic elements and as comprising nonmanagerial intellectuals as well. For Gouldner, New Class intellectuals had come to monopolize the “culture of critical discourse,” emerging as a somewhat flawed “universal class” with its own specific project of social reconstruction and domination.

Most Marxists, however, denied that the new middle class of unproductive but “socially reproductive” salaried workers possessed a determinate set of homogeneous interests or was capable of articulating a coherent class project distinct from the bourgeoisie and the working class. In one influential and controversial formulation proposed by Barbara and John Ehrenreich (1978), such elements constituted a “Professional-Managerial Class … consisting of salaried mental workers who do not own the means of production and whose major function in the social division of labor may be described broadly as the reproduction of capitalist culture and capitalist social relations.” But this class was seen as extremely diverse, and the Ehrenreichs did not regard it as a truly independent factor in the class dynamics of modern capitalist or post-capitalist societies. Other Marxists denied that the professional and managerial strata constituted a class at all, insisting instead that they occupied “contradictory locations” within class relations (as in the formulation by Erik Olin Wright). It was commonly assumed that in the course of class struggle between capital and labor, this new middle class would tend to polarize in terms of their allegiances to the more fundamental social classes defining capitalist society.
Marxist theorists of this persuasion also typically denied that the ruling bureaucratic oligarchies within the communist states constituted a new managerial ruling class, regarding them either as remnants of the old class society within social formations in transition to classless communism or as a “state capitalist” ruling class. Many asserted the thesis of Russian revolutionary leader Leon Trotsky in The Revolution Betrayed (1936) that the Stalinist oligarchy was a brittle and dysfunctional stratum lacking the attributes of a fully formed social class and destined to fragmentation as the Soviet Union either moved forward to socialism (through an international extension of the socialist revolution) or backward to capitalism (the inevitable result of a too-prolonged isolation of the Soviet “workers state” from the international division of labor).

THE FUTURE OF THE CONCEPT

The idea of an ascendant managerial class capable of exercising a class hegemony over advanced, industrialized societies lost favor in the new era of corporate downsizing, neoliberalism and capitalist globalization that opened in the 1980s. Nevertheless, the role of intellectual, managerial, and technocratic elements in assuring the continuous reproduction of capitalist culture and social relations remains a vital one. In particular, since the advent of Frederick Taylor’s project of “scientific management,” capital has been reliant on a special stratum of salaried “hired guns” to safeguard its interests against the demands and struggles of the wage-earning class. However, with the shift of radical social analysis from capital-labor relations to “identity politics,” increasing attention has been devoted to the persistent obstacles to entry into the intellectual elites and upper management experienced by women, racial minorities, and others designated as “undesirables” (see, for example, Darity 1996). The intersections of class, race, and gender provide a rich new field of inquiry for a concept that has proven to be both resilient and acutely susceptible to the vagaries of ideological fashion.

Mandel, Ernest

1923–1995

Ernest Mandel, a professor at the Free University of Brussels, was a renowned Marxist scholar and one of the best-known Trotskyists of the second half of the twentieth century. In the 1960s he emerged as a leading figure of one of several organizational contenders to the mantle of the Fourth International, the “world party” founded by the exiled Russian communist leader Leon Trotsky in 1938 with the dual aim of overthrowing world capitalism and combating the Stalinist “bureaucratic degeneration” of Russia’s socialist revolution of 1917.

Mandel’s commitment to achieving a worldwide socialist democracy profoundly influenced all aspects of his scholarship. He wrote some thirty books and about two thousand articles, including such major works as Marxist Economic Theory (1968), From Stalinism to Eurocommunism (1978), Late Capitalism (1975), Trotsky as Alternative (1995), and Power and Money: A Marxist Theory of Bureaucracy (1992). Mandel’s economic works were centrally concerned with demonstrating the continuing relevance of Karl Marx’s critical analysis of the capitalist mode of production to both the postwar boom of the 1950s and 1960s and to the subsequent period of stagflation and declining profitability that had begun in the early 1970s. In Late Capitalism, he sought to show how the inexorable laws of motion of advanced capitalism must eventually result in severe economic crises, which in turn would give a major impetus to the global class struggle between capital and labor. While advocating a multicausal explanation of capitalist economic crisis, he also defended Marx’s view that the average rate of profit was the key variable determining
the fortunes of capitalist societies and that its tendency to fall was largely due to technological innovations that displaced living wage labor (the sole source of surplus value) from the capitalist production process.

In his Marshall Lectures delivered at Cambridge University in 1978 (published in 1980 as *Long Waves of Capitalist Development*), Mandel expanded on an original argument, first advanced in *Late Capitalism*, that the history of the capitalist mode of production had been characterized not only by the short-term industrial cycles analyzed by Marx, but also by four successive “long periods” of development, each characterized by a particular form of productive technology. The duration of each period was approximately fifty years, and each could be subdivided into an initial long wave of accelerating economic growth, corresponding to generally high rates of profit, and a subsequent long wave of decelerating growth, marked by lower profit rates.

The argument owed something to the Russian economist Nikolai Kondratiev’s theory of long cycles of economic development, but departed from it by insisting that an expansionist wave following a wave of stagnation is not due to a corrective mechanism inherent in the functioning of capitalism, but depends on strictly noneconomic factors such as wars of conquest and decisive victories by capital over labor in the class struggle. The issue of whether capitalism had passed from a wave of stagnation to one of expansion by the twenty-first century sparked controversy among those adhering to Mandel’s theory of long waves.

Non-Marxists sometimes criticized Mandel for allowing his dedication to Marxist orthodoxy to constrain an otherwise creative and fertile intellect. Marxist critics complained about his theoretical eclecticism, historical objectivism, and political opportunism. Nevertheless, his writings and personal example left a deep impression on many scholars and activists shaped by the youth radicalization of the 1960s.

**MANDELA, NELSON**

1918–

Nelson Rolihlahla Mandela is South Africa’s iconic elder statesman and winner of the 1993 Nobel Peace Prize. After almost fifty years of antiapartheid activism as a leader in the African National Congress (ANC), including over twenty-seven years in prison (1962–1990), Mandela became South Africa’s first democratically elected president in 1994. Since stepping down from the presidency in 1999, he has continued to play a visible role in South African and international affairs.

Born into the royal Tembu family near Umtata in the Transkei, Mandela attended missionary schools prior to entering Fort Hare University College in 1939. Suspended for participation in student protests in 1940, he moved to Johannesburg, completing a bachelor’s degree through correspondence in 1942. Working and studying part time, he qualified as an attorney through apprenticeship and passage of the qualifying exam in 1952.

His political career began in 1944, when he became a founding member of the Youth League of the ANC. He was prominent in efforts to galvanize the senior ANC to greater militancy that culminated in passage of the Program of Action in 1949. Dropping his opposition to collaboration with communists and Indian nationalists in the wake of their determined opposition to the relentless post-1948 implementation of apartheid, Mandela was at the center of the ANC-led Defiance Campaign (1952–1953),单元ing Africans and antiapartheid volunteers of all races and ideological persuasions in nonviolent protest actions. Elected provincial president of the Transvaal ANC and deputy national president of the ANC in 1953, he was banned from political activity by the government and forced to resign. For the remainder of the decade, he concentrated on organizational activities behind the scenes. Only during the long-running treason trial (1956–1961) of 156 ANC members and their non-African allies was Mandela highly visible as lawyer, witness, and spokesman from the dock.

After the defendants in the treason trial were acquitted, Mandela went underground to organize support for unsuccessful mass protests in May 1961. Popularly dubbed the “Black Pimpernel,” surfacing sporadically in South Africa and during a seven-month overseas trip, he evaded arrest and prison for seventeen months. While underground, he participated in clandestine meetings of the ANC (banned in 1960 under the Unlawful Organizations Act in the wake of the Sharpeville massacre) at which the ANC decided to end its policy of nonviolence. Mandela and other leaders of the banned ANC and its also proscribed ally, the Communist Party, then formed a unit called Umkhonto we Sizwe (Spear of the Nation) in mid-1961 to conduct sabotage and prepare for eventual guerrilla warfare. In August 1962 Mandela was apprehended by the police in Howick, Natal, and in November 1962 he was sentenced to five years in prison for incitement to strike and leaving the country illegally.
Subsequent to the separate arrest of nine other leaders at the underground Rivonia headquarters of Umkhonto we Sizwe in Johannesburg in July 1963, Mandela was brought from Robben Island prison to face trial with them on charges of sabotage. In the glare of worldwide publicity at the end of the trial, he delivered a dramatic final statement from the dock, concluding that “the ideal of a democratic and free society … is an ideal for which I am prepared to die.”

Receiving a life sentence (instead of the death sentence that could have been passed), Mandela returned to Robben Island and became the world's most famous political prisoner. Despite South African efforts to black out news about him, the world increasingly became aware of his assertive demands that the government adhere to prison regulations and his leadership of fellow inmates across the political spectrum. Transferred to Pollsmoor prison on the mainland in 1982 and then to a cottage in Victor Verster prison in 1987, Mandela became the star of a deft and media-smart campaign for unconditional release from prison. Simultaneously, he conducted secret talks with government ministers to set the stage for negotiations to achieve majority rule.

Released unconditionally from prison on February 11, 1990, by the newly elected president F. W. de Klerk, Mandela immediately assumed the leadership of the ANC's negotiations with the Nationalist Party government. Against a backdrop of rising violence, he showed repeated willingness to compromise with former opponents without abandoning the goal of nonracial constitutional democracy based on one person, one vote. In November 1993 an agreement was reached on a constitution, and in December 1993 Mandela and de Klerk were jointly awarded the Nobel Peace Prize.

Victorious at the head of the ANC ticket in the country's first election open to all citizens, Mandela assumed the presidency of South Africa on May 10, 1994. During his five-year term, he won extraordinary respect at home and abroad for his advocacy and practice of national reconciliation. After completion of his presidency, he turned to international issues, successfully mediating ethnic strife in Burundi. He also spoke out strongly on HIV/AIDS, urging both the South African government and the international community to greater commitment. In June 2004, shortly before his eighty-sixth birthday, he announced his retirement from public life.

MANDELA, WINNIE

1936–

Nomzamo Winifred Zanyiwe Madikizela was Columbus and Gertrude Madikizela's fifth child, born on September 26, 1936, in Pondoland Hills in Bizana (near Transkei), South Africa. Winnie's father encouraged her to complete a diploma at the prestigious Jan Hofmeyr School of Social Work in Johannesburg. She became the first black female social worker at Baragwanath Hospital. She would later complete a bachelor's degree in International Relations from the University of Witwatersrand. Winnie married political activist and leader of the African National Congress (ANC) Nelson Rolihlahla Mandela on June 14, 1958. Winnie and Nelson moved to Soweto and immediately began a life together fighting the oppressive apartheid regime of South Africa. Winnie became actively involved in the ANC Women's League and participated in protests against various obstructions to black South Africans' freedom, including the requirement for blacks to carry “passes” in order to travel within the country. Blacks that were caught without passes could be subjected to abuse and jail time. Nelson and Winnie were under tremendous scrutiny by the South African government. Nelson left the country to avoid being arrested for treason. He was arrested upon his return for inciting black South African workers to strike and for leaving the country without proper traveling documents. In 1962, Nelson would begin a twenty-eight year incarceration.

Winnie worked for the Johannesburg Child Welfare Society and was continually placed under numerous bans for her suspected affiliation with ANC. She was fired from various jobs due to repeated harassment of her employers by South African police. She also faced consistent bans inhibiting her ability to raise her two children, Zeni and Zindzi. In 1970, Winnie was detained for 491 days in Pretoria Prison before being released on house arrest. Frequent threats against Winnie's life, including a bomb explosion outside of her home, led her twelve-year-old daughter Zindzi to write a letter of appeal to the United Nations for her mother's protection. Winnie would be arrested and jailed two additional times, in 1974 and in 1976, after the Soweto student uprising against Bantu education led to the police beating and killing of many children. Winnie was viewed as an instigator and was
arrested under the Internal Security Act. Winnie became an executive member of the Federation of South African Women, the Black Parents Association, and continued supporting the efforts of the ANC. She inspired many black South Africans and was known as the "Mother of the Nation." After her release from jail in 1976, she was banished for nine years to a remote black township known as Brandfort. For a time, she lived with no heat, no toilet, and no running water in a three-room shack she shared with Zindzi. Her eldest daughter, Zeni, married Prince Thutmumuzi of Swaziland in 1978.

Winnie was linked with radical factions of ANC during the 1980s and her legacy became tarnished by several key incidents, which eventually led to her divorce in 1996 from then President Nelson Mandela. The incidents centered around a group of bodyguards she formed, known as the Mandela United Football Club. Winnie was implicated in the murder of fourteen-year-old ANC activist James "Stompie" Moeketsi and numerous other beatings and deaths associated with the Football Club. When she appeared before the Truth and Reconciliation Commission, Bishop Desmond Tutu (b. 1931) begged her to admit her mistakes and Winnie acquiesced with the words "things went horribly wrong." She was convicted on 43 counts of fraud in 2003 and is considered a leading anti-apartheid activist and controversial figure around the world.

MANIAS

The American Psychiatric Association (APA) defines mania as a period of unusually elated or irritable mood that is accompanied by at least three other symptoms (APA 2000). The symptoms of mania can include physical restlessness or overly active behavior; rapid speech or unusual talkativeness; racing thoughts; markedly diminished need for sleep (e.g., feeling rested after only a couple hours of sleep); inflated self-esteem; difficulty focusing attention; and excessive involvement in pleasurable activities without regard to undesirable consequences, such as reckless spending, sexual behavior, or driving. A manic episode is diagnosed if symptoms last for at least one week or lead to hospitalization, and if the symptoms are extreme enough to cause either distress or interference with social or occupational functioning. A person in a manic episode may feel invincible and enthusiastic, but family and friends may perceive manic activity as alarming.

The APA defines several other types of related episodes as well. Hypomania is milder than mania; it is diagnosed if the above symptoms are present for at least four days and produce noticeable changes in functioning without significant distress or impairment. Mixed episodes meet criteria for a full manic episode, but include concurrent depressive symptoms.

Bipolar disorders are defined based on the types of episodes experienced. Bipolar I disorder includes the presence of at least one lifetime manic or mixed episode. Bipolar II disorder is characterized by at least one lifetime episode of hypomania, along with at least one episode of depressive symptoms. Cyclothymia is defined by milder fluctuations of manic and depressive symptoms, which never meet the severity of full-blown manic or depressive episodes, but which are present at least 50 percent of the time for two years. The term bipolar reflects the fact that most (but not all) people with an episode of mania or hypomania will experience depressive episodes during their lifetime. No biological tests are used to diagnose bipolar disorder. Findings of large studies indicate that approximately 3.9 percent of people will meet diagnostic criteria for bipolar I or II disorders (Kessler et al. 2005), and that approximately 4.2 percent will meet diagnostic criteria for cyclothymia during their lifetime (Regeer et al. 2004).

Researchers have documented above-average rates of bipolar disorder among the world’s most famous artists, authors, and composers (Jamison 1993). Unaffected family members of people with the disorder appear to be more creative than those affected by the disorder (Richards et al. 1988). In addition, family members of those with the disorder appear to have elevated levels of accomplishment in their careers (Johnson 2005).

Despite these intriguing correlates, bipolar disorders remain among the most devastating of psychiatric conditions. Suicide rates among people hospitalized for bipolar I disorder are twelfe-fold higher than those in the general population (Harris and Barraclough 1997). Most people
remain unemployed a year after hospitalization for mania (Keck et al. 1998). As a consequence, bipolar disorders have been projected to become a leading cause of medical disability worldwide (Murray and Lopez 1996).

What causes this disorder? Bipolar disorder is one of the most genetic of psychiatric illnesses. Twin studies comparing rates of disorder in identical and fraternal twins suggest that 60 to 85 percent of the variability in whether or not people will develop bipolar I disorder is explained by genes (McGuffin et al. 2003). About 10 percent of the children of a parent with bipolar I disorder will develop a bipolar disorder. It is likely that a set of genes, rather than a single gene, contributes to cause the disorder.

Although there is no cure for bipolar disorder, medications are considered the best form of treatment. Medications are typically recommended throughout the life course, as people with one episode of mania are at extremely high risk for further episodes. Treatment guidelines recommend lithium as the medication of choice. Lithium has been shown to help prevent relapses, to reduce severity of episodes when they do occur, and to decrease suicidality. Unfortunately, many people find the side effects of lithium difficult to tolerate. Other medications, such as antiseizure and antipsychotic medications, have been licensed by the U.S. Food and Drug Administration for the treatment of mania. These treatments are often supplemented with medications to treat depressive symptoms (although antidepressant medications are not recommended without a mood stabilizer because they can trigger manic symptoms).

Although medicine is the primary approach to treatment, stressors and sleep loss can trigger episodes of bipolar disorder. Given this, as well as the devastating consequences of the disorder, psychosocial treatments can be used to supplement medication. Psychoeducation and family therapy can help prevent hospitalization, and cognitive therapy, focused on changing self-critical thoughts, helps reduce the risk of depression (Miklowitz and Johnson 2006).

MANIC DEPRESSION

Many lay people use the name manic depression to refer to a disorder that is more formally called bipolar disorder within the diagnostic system of the American Psychiatric Association. In this formal diagnostic system, there are three forms of bipolar disorder. Bipolar I disorder, the most severe form, is defined by a single episode of mania. Manic episodes are characterized by a period of expansive, elevated, or irritable moods, along with such symptoms as diminished need for sleep, rapid speech, grandiosity, agitation or increased activity, racing thoughts, and increased engagement in pleasurable activities that have potential to cause trouble. The symptoms must last for at least one week and create severe impairment. Bipolar II disorder is a milder form of the disorder, defined on the basis of hypomania and recurrent depression. Hypomania is characterized by the same set of symptoms as mania, but symptoms must only last for four days and do not create severe impairment. Cyclothymia is defined by frequent ups and downs that are not severe enough to meet the criteria for hypomania or mania.
Manic Depression

Two measures commonly used to verify diagnoses within research studies include Michael B. First and M. Gibbons’s 2004 Structured Clinical Interview for DSM-IV (Diagnostic and Statistical Manual of Mental Disorders, 4th ed.), and Jean Endicott and Robert L. Spitzer’s 1978 Schedule for Affective Disorders and Schizophrenia. No biological markers are available to aid with diagnosis.

About 1 percent of the population experiences bipolar I disorder; it was estimated in 2005 by Ronald C. Kessler et al. that bipolar II disorder also affects approximately 1 percent of the population. Cyclothymia may affect 4 percent of the population, according to a 2004 study by E. J. Regeer et al. The vast majority of people with a single episode of mania will experience another episode during their lifetime, many within five years, reported Michael J. Gitlin et al. in 1995. A 2002 report by Lewis L. Judd et al. said that mild symptoms lingering between episodes are common. The median time of onset for this disorder has been estimated at twenty-five years of age, according to the report by Kessler et al., but at least 25 percent of affected people report that episodes began by age seventeen.

It is well established that bipolar disorder is biologically based: heritability accounts for as much as 85 percent of whether people develop mania, according to a 2003 report from Peter McGuffin et al. Neurobiological research in 2003 by Craig A. Stockmeier suggests that a set of brain regions, modulated by dopamine and serotonin, are involved in the disorder. Psychosocial variables, including negative life events, negative cognition, and family hostility and criticism can increase the risk of depressive episodes within this disorder, per several reports (Burzlaff and Hooley 1998; Monroe et al. 2001; Alloy et al. 2000). Sleep loss and events involving goal attainment can predict increases in mania over time (Johnson 2005a, 2005b; Malkoff-Schwartz et al. 1998, 2000).

Historically, treatments for this disorder, including psychotherapy alone or hospitalization, were not very effective. The discovery of lithium’s mood-stabilizing effects led to dramatic gains in outcome. The dominant treatment approach is mood-stabilizing medication. The first-line treatment recommendation remains lithium, but if side effects are difficult to tolerate, anticonvulsant medications are also useful mood stabilizers. Antidepressants are often added to combat depression, but not without a mood stabilizer because antidepressants can provoke manic symptoms when administered alone (Alshuler et al. 1995; Goldberg and Whiteside 2002). Antipsychotic medications can address psychotic or agitation symptoms. Research in 2004 by Sheri L. Johnson and Robert L. Leahy indicates that family or individual talk therapy can be helpful supplements to medication.

**MANIFOLDS**

In mathematics, a manifold is a space that looks like a Euclidean space, locally around every point. Since a set is defined by its elements, two spaces can be seen as equivalent if there is a bijection (one-to-one correspondence) between them. There are different versions of this equivalence, depending on the structure of the bijection. When the two spaces are topological, the bijection is a homeomorphism if it is continuous and has a continuous inverse. If both spaces are Euclidean, the bijection is a C^k diffeomorphism if both it and its inverse are (or can be extended to be) of class C^k. A topological space is a J-dimensional topological manifold if for every point there exists a homeomorphism from some open subset of the J-dimensional Euclidean space to an open neighborhood of the point. If, in the Euclidean case, what one has is a C^k diffeomorphism, then the space is a C^k differentiable manifold.

A manifold has the property that, at every point, one can find a neighborhood that is just a transformation of a Euclidean space, preserving topological and/or differential properties. An example of this type of transformation is from a circle to an ellipse, whereas going to a number eight would not be bijective, to a line would violate continuity, and to a triangle would violate differentiability.

Differentiable manifolds are the natural objects for the application of calculus, and the study of that application, differential topology, has proved useful in economic theory. These techniques were introduced to economics in 1970 by Gerard Debreu’s proof that, generically in the space of exchange economies (that is, in almost all of them), competitive equilibria are isolated from one another. The argument is an application of the Transversal Density Theorem of differential topology.

Later, Darrel Duffie and Wayne Shafer used Grassmanian manifolds (the sets of linear subspaces of a given Euclidean space) to show that in exchange economies subject to uncertainty and endowed with real assets (those whose payoffs depend on the prices of commodities), a competitive equilibrium generically exists. This application was necessary because the dependence of payoffs on prices makes the space of revenue transfers across states of nature variable. The idea of Duffie and Shafer was to break that dependence, effectively weakening the concept of equilibrium but allowing the use of the manifold structure of the Grassmanian to guarantee its existence, and then to show that, generically, the weaker equilibrium is indeed equilibrium.

Another remarkable application of techniques of differential topology in economics is the proof by John Geanakoplos and Herakles Polemarchakis that in a generic economy with uninsurable risks, just by changing their trade in assets, and then competitively trading in commodity markets, all individuals could be better off than at the competitive equilibrium allocation. This result was also obtained from the Transversal Density Theorem.

But perhaps the most visible application of the concept is the result, claimed by Yves Balasko, that in economies described by the preferences of the individuals, the set of pairs of profiles of endowments and associated competitive equilibrium prices is a differentiable manifold. After this result, the equilibrium set of an economy is usually referred to as equilibrium manifold.

MANKILLER, WILMA
1945–

Wilma Pearl Mankiller struggled successfully against male dominance, white privilege, and significant health problems to become the first female principal chief of the Cherokee Nation. Her accomplishments occurred in a social context of poverty, failed federal government relocation programs, and social protest movements for American Indians. Her ability to secure government funding for her tribe reflected movement toward assimilation and societal integration for women and American Indians. Mankiller's support for Indian and female empowerment included social movements, politics, and protest. Thus, her legacy may also be viewed through the prism of resistance to oppression and oppositional culture.

Mankiller was born on November 18, 1945, in Tahlequah, Oklahoma, the sixth of eleven children of Charley Mankiller and Clara Irene Sitton. Her father's family had endured the Trail of Tears, the forced removal of Cherokees in 1839 from the Tennessee Valley to Oklahoma, where they lived in severe poverty and had to conduct tribal ceremonies in secret. Despite these hardships, her family remained a source of comfort for her and taught her to be proud of her heritage and her family name, Mankiller, which was a Cherokee title given to a person who safeguarded a Cherokee village.

In 1956, her family was relocated to San Francisco, California, as part of the Bureau of Indian Affairs' Indian Relocation Program, which attempted to sever Native Americans' ties with their land and culture, thus helping the U.S. government avoid responsibility for the institutionalized oppression of American Indians. Despite facing poverty, prejudice, and discrimination, Mankiller found inspiration and support at the American Indian Center in San Francisco. As a young adult, she took a job at a financial company, married, and had two daughters.

Her activism was sparked by the 1969 to 1971 seizure of Alcatraz Island by Native Americans. She and others in her family took part in the protest as a way to draw attention to the plight of Native Americans. Through this experience, Mankiller met and befriended many of the leaders of Native American empowerment movements. Soon afterward, Mankiller was diagnosed with polycystic kidney disease. Despite the diagnosis, Mankiller directed the Native American Youth Center in Oakland and continued her involvement in social protest movements on behalf of American Indians. She helped the Pit River tribe regain tribal land from the Pacific Gas and Electric Company, which tried to assert ownership over their land. Mankiller worked for the tribe for five years, organized a legal defense fund, and researched treaty rights and international law to aid their cause.

More interested in activism than in being a housewife, Mankiller divorced her husband and moved back to Oklahoma with her children in 1977. She used her skills acquired in San Francisco to work for the Cherokee Nation of Oklahoma as an economic stimulus coordinator. In 1981, Mankiller founded and directed the Cherokee Nation Community Development Department, which received acclaim for rehabilitating the small Cherokee community of Bell, Oklahoma. She accomplished this despite recovering from a serious car accident that killed a friend and receiving treatment for systemic myasthenia gravis, a form of muscular dystrophy.

In 1983, she ran for deputy chief of the Cherokee Nation. She won the election and became the Cherokee Nation's first female deputy chief despite death threats because of her sex. She was appointed the first female principal chief of the Cherokee Nation in 1985 after the presiding principal chief was nominated to lead the Bureau of Indian Affairs. In 1987, she won a tough election and, while actively leading the Cherokee Nation, underwent a kidney transplant in 1990. In 1991, Mankiller was reelected principal chief with 83 percent of the votes cast. In 1995, she chose not to run again and instead accepted a fellowship at Dartmouth College.

During her term as Cherokee chief, tribal revenue increased, $20 million was secured for construction projects, an $8 million Job Corps center was created, and funding was secured for programs aiding women and children and to reform the Cherokee judiciary. She also developed economic and educational empowerment programs in which women and men worked collectively for community improvement under the Cherokee tradition of gadugi, which emphasizes gender equity. In 1996, she was diagnosed with lymphoma and received treatment while continuing to write, edit, and participate in community organizations. In 1998, she was awarded the Presidential Medal of Freedom.

Wilma Mankiller nurtured economic development for American Indians and paved new paths to leadership for women of color. She exemplifies greater economic and political assimilation for women and American Indians. Mankiller's significance also rests in resistance to institutional and cultural racism and sexism through embracing social protest and oppositional culture.
MANNHEIM, KARL
1893–1947

Karl Mannheim was a Hungarian philosopher and sociologist who is usually credited with having established the sociology of knowledge as an autonomous field of inquiry—as opposed to, say, an application of Marxist or phenomenological sociology. Mannheim’s intellectual trajectory resembled that of his contemporary, Georg Lukács (1885–1971), with whom he remained friends until the rise of Nazism. Whereas Mannheim fled to London, Lukács fled to Moscow, and their politics diverged accordingly from their original common Marxist roots. Both were grounded in the philosophy of culture and were early influenced by Georg Simmel’s (1858–1918) conception of sociology as the science of forms of life. Each tried to ground a conception of objectivity from the “relationist” epistemology common to Karl Marx (1818–1883) and Simmel. This produced an interesting contrast in privileged standpoints and, implicitly, the vanguard of progressive politics. In response to Lukács’s “proletarian standpoint,” where workers were understood as integral to, yet alienated from, the means of production, Mannheim proposed a “free-floating intelligentsia,” an increasing segment of the middle class whose alienation reflects its detachment from the means of production.

Mannheim’s sociology of knowledge was refined through a series of debates in both the German- and English-speaking worlds. Prior to the publication of his major work, Ideology and Utopia (1929), Mannheim corresponded with the art historian Erwin Panofsky (1892–1968) over the sense of “historicism” required of cultural interpretation. In contrast to Panofsky’s view of art as the unique synthesis of various ongoing traditions, Mannheim stressed art’s ability to capture the common experience of a generation. Indeed, “ideology and utopia” referred to contrasting attitudes toward history that might be shared by a generation: the backward-looking (conservative) ideology and the forward-looking (progressive) utopia.

Over his career, Mannheim cast this perspective in increasingly normative terms, culminating in the proposal of new modes of political education and broadcast media capable of instilling social democratic attitudes in the generation entrusted with reconstructing post–World War II Europe. Here he crossed swords with both liberals and elitists, including fellow émigrés Michael Polanyi (1891–1976) and Karl Popper (1902–1994), as well as T. S. Eliot (1888–1965), with whom Mannheim maintained a friendly rivalry until his death.

Two seminal theses in the sociology of knowledge are due to Mannheim: (1) a knowledge practice’s validity is relative to its capacity to confer legitimacy on a particular social order; and (2) the social conditioning of a knowledge practice that is valid according to standard methodological criteria can be demonstrated by showing how the practice helps to reproduce—and sometimes even constitute—the criteria by which it is judged valid. Both theses remain controversial because they imply that the sociology of knowledge can challenge the philosophical theory of knowledge, epistemology, on its own grounds. Mannheim’s challenge was later taken up by “social epistemology.”

MAO ZEDONG
1893–1976

Mao Zedong (previously Mao Tse-tung) is undisputedly the preeminent figure in modern Chinese history, and also
Mao Zedong

a commanding presence in the history of the twentieth century. The Mao-led Communist revolution in 1949 ended China’s century of humiliation and laid the foundations of the rapidly developing nation of the early twenty-first century. But Mao also created much unnecessary social turmoil in the latter part of his political career; he did not know when to exit the historical stage gracefully. As a result, most Chinese today have a mixed view of Mao—a great leader who united and rejuvenated their massive country, but also one who left considerable human suffering in his wake. Mao is often compared to Qin Shihuangdi (259 BCE–210 BCE), the First Emperor of Qin, a brilliant but ruthless leader who created the first unified Chinese empire in 221 BCE.

Mao was a complex personality who was torn between admiration for China’s past imperial glory and despair at its parlous condition in the closing decades of the nineteenth century, when he was born. As a young man, he struggled to reconcile the dichotomy in his mind (and in the minds of many others in his generation) between China’s traditional civilization and the increasing demands of a modern world dominated by the advanced nations of Europe and North America. In Marxist-Leninist theory, Mao discovered a penetrating Western critique of the West, which enabled him to adopt many of its revolutionary premises (and promises) without abandoning China’s own impressive cultural heritage. In direct intellectual descent from Mao, China’s succeeding leaders continue to claim they are building socialism with Chinese characteristics, a somewhat ambiguous concept that has yet to be fully articulated, which (at least in the narrower area of economics) is often referred to as market socialism.

RISE TO POWER

Mao was born on December 26 into a moderately well-off peasant family in the village of Shaoshan in Xiangtan County, Hunan province, in south-central China, not far from the provincial capital of Changsha. He developed an early interest in political and international affairs, and his years at the First Provincial Normal School in Changsha, where he studied to be a teacher, brought him into contact with young men and women from all over the province. Seeking a wider stage after graduation, Mao set out for Beijing in 1918, where he studied and worked part-time in the library at Peking University, the nation’s premier institution of higher education, and, at the time, a hotbed of radical political thinking among many of the faculty and students.

Mao took an active interest in the student-inspired May Fourth movement, which sparked off a country-wide nationalist upsurge directed against unwanted European and Japanese influence in China. Soon after, Mao declared himself to be a Marxist-Leninist, without actually undertaking a thorough study of either the revolutionary doctrine or the Russian Revolution in 1917. After a short period as an elementary school principal and political activist back home in Hunan, he became a founding member of the Chinese Communist Party, which was formally established in Shanghai on July 23, 1921.

Consolidating Power Mao’s rural background gave him a special interest in the peasantry, and he was often at odds with his more urban-oriented colleagues. In early 1927, after an intensive study of rural conditions in his native province, Mao wrote his seminal “Report on an Investigation of the Peasant Movement in Hunan,” in which he predicted that the peasant masses would soon rise up and sweep away the old, feudal system of land ownership that exploited and oppressed them. The Communists, he argued, should lead the peasants or get out of the way. Chiang Kai-shek’s (1887–1975) bloody coup in the spring of 1927 effectively destroyed the Communist organizations in Shanghai and other major cities, forcing them to find refuge in Jiangxi province, in the mountainous hinterland in south-central China, adjacent to Hunan where Mao had been born and raised. Mao was elected chairman of the new Jiangxi Soviet (local Communist government) in this isolated base area, but soon lost power to the Returned Student group (a reference to their study in Moscow), which took over party leadership and pushed him aside.

Mao finally came into his own during the famous Long March in 1934 to 1936, when the Communists had to flee from Nationalist leader Chiang Kai-shek’s fifth and finally successful military encirclement campaign to surround their base area and destroy them. At the decisive Zunyi conference in January 1935, in the early part of this arduous 6,000-mile trek, Mao was recognized as the political and military leader of the Communist movement. At the Communists’ new base area in Yan’an, a small county seat in China’s arid northwest region, Mao built an elaborate system of ideology, organization, guerrilla warfare, and rural recruitment that led quickly to the emergence of a powerful political movement, backed up by its own military forces (the Red Army). Both the party and the army grew rapidly during the war against Japan, which had invaded China in July 1937, and the Communists emerged as a formidable competitor for state power with the Nationalists.

By the end of the war in 1945, Mao was hailed as the Party’s leading political and military strategist, and, coincidentally, its preeminent ideological thinker. What was now called Mao Zedong thought was said to represent the Sinification of Marxism, that is to say, the adaptation of Marxist theory to China’s actual historical conditions.
Mao’s thought, reinforced through a powerful personality cult and an oppressive rectification campaign to tame his critics, was to become the ideological foundation of the Chinese Communist movement in subsequent years.

SUCCESS—AND FAILURE

Despite unfavorable odds, the Red Army (renamed the People’s Liberation Army) employed superior strategic tactics to defeat the Nationalists in the civil war (1946–1949). Mao wasted no time in consolidating Communist rule; he proclaimed the founding of the People’s Republic of China on October 1, 1949, and moved decisively to consolidate its borders and occupy and reintegrate Tibet. His intention was not merely to rebuild the shattered nation, but also transform it, which, with a staggering population of over 400 million, was the world’s largest. In late 1949 to early 1950, Mao traveled to Moscow (his first trip abroad) and signed an alliance with the Soviets; but Mao and Soviet leader Joseph Stalin (1879–1953) neither liked nor trusted each other and their relationship was to prove unstable. The Korean War (1950–1953) could not have come at a worse time for the new regime, but at great cost Chinese troops succeeded in repulsing the U.S. advance into the north, near the Yalu River on the Chinese border.

Despite these international concerns, Mao launched a wide-ranging program of reconstruction and nationalization in major industrial and commercial cities such as Shanghai and Guangzhou (Canton). In the countryside, land was confiscated from the landlord class, many of whom were summarily executed by makeshift tribunals, and land passed (if only briefly) into the hands of the ordinary peasants. A comprehensive range of social reforms was also launched, including marriage reform favoring the female; a crackdown on crime, drugs, and prostitution; and clean-up campaigns targeted at government and business corruption. Although U.S. intervention had placed Taiwan beyond their grasp, by the mid to late-1950s things had gone very well for the Communists, and for this much credit must go to Mao and his fellow party leaders.

But Mao had ever more ambitious plans. He wanted to speed up the pace of economic growth, based on industrial development and the collectivization of agriculture; and he wanted to emancipate China from the bonds of the Soviet alliance, which he found increasingly restrictive. Unfortunately it was at this juncture, in the late 1950s, that Mao’s hitherto deft political touch began to fail him and he launched two disastrous political campaigns that convulsed the country and ultimately damaged his reputation. The Great Leap Forward in 1958, calling for the establishment of small backyard factories in the towns and giant people’s communes (consolidated operative enterprises) in the countryside, resulted in an economic lurch backward. The consequent three bitter years (1959–1961) saw rural peasants perish in the millions due to harsh conditions for the very young, the very old, and the disadvantaged. Chastened, and under criticism from his more moderate colleagues, Mao agreed to step back from the forefront of leadership; he turned his attention to the growing ideological polemic marking the growing Sino-Soviet split and left it to others to repair the untold damage at home.

In his heart, Mao believed that the Great Leap Forward had failed largely because too many party officials (cadres) did not boldly implement his policies; disparagingly, he compared them to old women tottering about in bound feet. He decided to purge these revisionist (pro-Soviet) officials and others said to be taking the capitalist road (more open to Europe and North America generally) from positions of authority. Mao and his military faction (the Gang of Four) called upon the nation’s youth (primarily high school and university students) to rise up and call the errant officials to account. The result was the Great Proletarian Cultural Revolution, which witnessed the unusual spectacle of the top Communist leader declaring war on his own party organization. Millions of inflamed students and others donned Red Guard armbands, and, waving the Little Red Book (1966) of selected Mao quotations, they proceeded to carry out their assigned mission. The campaign tore the country apart from 1966 to 1969, forcing Mao to call for military intervention to restore order, and it dragged on destructively until his death in 1976. Still, from the perspective of foreign policy, the Cultural Revolution’s sharp anti-Soviet orientation succeeded in liberating China from its underlying dependency on the Soviet Union, and prepared the nation for a more independent role in international affairs in the years ahead.

A BEGINNING, AND AN END

Despite his miscalculations with the Great Leap Forward and the Cultural Revolution, Mao wisely decided to play the American card in order to counterbalance growing Soviet military power on the conflict-prone Chinese border. With the surprise invitation to a U.S. table tennis team then in Japan to visit China, Mao set in motion the ping-pong diplomacy that led to U.S. president Richard Nixon’s state visit to China in February 1972, which culminated in the landmark Shanghai communiqué calling for a more constructive relationship between the countries. Mao and Nixon toasted each other cordially in the Great Hall of the People in Beijing, laying to rest a generation of bitter enmity and setting the stage for the remarkable flowering of Sino-American relations that has continued into the early twenty-first century. It was to be
Mao's final hurrah; already in declining health (possibly suffering from Parkinson's disease), he gradually faded from the scene and passed away peacefully at age eighty-two on September 9, 1976.

In an official assessment of his lengthy career, the Communist Party hailed Mao as an illustrious national hero who laid the foundations of the new China, but at the same time a tragic figure with all too human frailties. Mao is buried in a grand mausoleum in Tiananmen Square in Beijing and he enjoys considerable popular approbation despite his rather clouded historical record. But while many people revere Mao, many others revile him, as they do the First Emperor of Qin, who lived some two thousand years earlier. For most Chinese though, many of whom were born well after Mao’s death, he remains the human embodiment of China’s national regeneration and its reemergence as a great world power.

English historian Lord Acton (1834–1902), in his famous observation on power, concluded that “great men are almost always bad men,” and, in the case of Mao, there is considerable truth to this. Mao was a romantic visionary who set himself seemingly impossible goals, but he had the necessary qualities of leadership, persistence, and ruthlessness to reach them, at least to a degree. In addition to his political and military prowess, he is also considered a talented calligrapher and poet in the classical style, and he left behind a small corpus of work that is generally well regarded. But he was also something of an uncouth peasant who lacked personal polish, could be vulgar in his choice of words, and (even in his declining years) overly enjoyed the company of young women. As he aged, he became increasingly out of touch with political reality, vainly attempting to force the entire nation onto the Procrustean bed of his own ideological convictions (ideological fantasies, some would say).

Will history remember Mao Zedong? Undoubtedly, for Mao occupies a historical position comparable to individuals such as Alexander the Great, Julius Caesar, Genghis Khan, Napoleon Bonaparte, and Qin Shihuangdi—these individuals were a frustrating mix of good and bad, but they all left a distinctive imprint on their own historical ages. Like playwright William Shakespeare’s Caesar, they “bestrode the narrow world like a Colossus,” and to this day their achievements and failures are enshrined in countless volumes for future generations to read and ponder. The same will quite likely be true of Mao Zedong.

MAOISM

Maoism is an influential revolutionary ideology of the twentieth century. The term Maoism, despite its originating from the name of the People’s Republic of China’s former leader Mao Zedong, is used primarily outside of mainland China. The Communist Party of China (CPC) uses Mao Zedong Thought as its official ideology. Although Maoism is only a derivation of Marxism and Leninism, its impact has been worldwide. Maoism continues to inspire international Maoists everywhere—especially in Asia and Latin America—even as the Chinese have been moving increasingly away from it.

The crux of Maoism is a belief that Marxism and Leninism can be adapted to suit the conditions of developing countries in their struggle against capitalism and imperialism. According to Karl Marx, a Communist revolution will be organized by advanced productive forces, such as industrial workers, and is possible only in an advanced capitalist society. Chinese Communist leader Mao Zedong, however, believed that rural revolutions in a traditional society can become a stepping-stone for an advanced social revolution, and peasants can be allies of the industrial workers and thus should play a pivotal role in erecting socialism and communism. During the lengthy military struggle in the rural areas of China, Mao formulated his theory of New Democratic Revolution.

Mao’s theory of revolution is based on the guerrilla war strategy, a disciplined Leninist party, and the united front. First of all, Mao believed that “political power comes from the barrel of a gun.” He and his comrades developed the strategy of rural-based guerrilla warfare and fought the nationalist government in the countryside for two decades. This strategy provided a practical solution for a smaller and weaker revolutionary force to defeat a much stronger and powerful state power. During World War II (1939–1945), Mao further extended his theory into the strategy of the “protracted people’s war,” designed to mobilize a total, yet prolonged, war to figuratively bleed the Japanese invaders to death.
Second, Mao emphasized the importance of a disciplined, elitist political party with absolute control over a revolutionary army. He developed doctrines such as democratic centralism, mass line, and criticism and self-criticism. All of these doctrines have become operational principles of the CPC. Finally, while stressing the need for the leadership of the CPC, Mao embraced a corporatist strategy to extend the party control to other political parties and groups. His theory of united front appears to raise the status of many smaller parties from opposition to collaborative and participating parties, yet it denies these parties the right to become competitors with the CPC, and thus lays the groundwork for the corporatist party-state after 1949. For all these contributions, the CPC formally adopted Mao Zedong Thought as its official doctrine in the Seventh Party Congress of the CPC held in Yanan in 1945.

In his early revolutionary career, Mao was a populist practitioner of Marxism rather than a dogmatic follower. Mao's success in using his military strategy to seize political power in a big country such as China established Mao's charismatic legitimacy in China and throughout the developing world. In his later life, however, Mao became an ardent defender of Marxism after the death of Joseph Stalin. In his fight against the so-called revisionists, such as the Communist leader Nikita Khrushchev in the Soviet Union, Mao apparently became more dogmatic. He defended Stalin and was unrepentant in his emphasis on the theory of “a continued revolution under proletarian dictatorship.” Mao and his supporters believed that an important task of the revolution was to carry out the proletarian dictatorship and class struggle against old and new bourgeoisie.

Maoism also contains some utopian elements. Mao believed that industrialization and modernization could go hand in hand with socialist transformation. The ambitious Great Leap Forward program (launched in 1958) tried unrealistically to speed up the industrialization process, but suffered a major setback. Nevertheless, this did not stop Mao from launching another major political campaign, the Great Proletarian Cultural Revolution (1966–1976), to crush leaders “who are taking the capitalist road,” and to transform political, social, and cultural superstructures that were considered to be unfitting with a socialist economy. Mao's quotation books (such as what became known in English as “The Little Red Book”) became a spiritual guide for the millions of young students (Red Guards) who waged a war on the establishment. The subsequent chaos was eventually put to an end after Mao's death in 1976.

Although Mao Zedong Thought continues to be upheld as the CPC’s official ideology, the radical and utopian elements have been discredited and revised. Worldwide, Maoism is still influential. The Maoist International Movement in the United States still supports a Maoist world revolution, and the Revolutionary Internationalism Movement continues to believe that the strategy of people's war is an effective means of Marxist revolution.

**MAQUILADORAS**

Although the term *maquiladora* or *maquila* is often used interchangeably with *export assembly firm*, it refers to a company operating under a very specific tax regime initiated by the Mexican government in 1969, and it is applicable to only one type of export production first established in communities near the U.S.-Mexico border. The official definition of the maquiladora regime defines it as “temporary importation of goods necessary for the transformation, elaboration, or repair of products destined to be exported, without taxes [being levied] on these temporary imports” (de la O 2002, p. 200).

**HISTORY OF THE MAQUILADORA**

In September 1942, Mexico and the United States agreed to the Bracero Program in an attempt to alleviate wartime U.S. labor shortages in agriculture and other areas. Approximately 5 million Mexican men participated in this guest worker (bracero) program until it ended in 1964. With the mechanization of agriculture in the United States and the decrease in demand for Mexican labor, the Mexican government began planning alternate sources of employment. During a 1964 tour of the Far East, Minister of Industry and Commerce Campos Salas was introduced to the notion of export production zones. He envisioned this as an alternative for Mexico’s economic development.

In December 1964, the United States unilaterally canceled the Bracero Program. As many as two hundred thousand braceros, comprising 40 to 50 percent of the
border population, found themselves without jobs, leading to a buildup of social unrest. In response, the Mexican government inaugurated the Border Industrialization Program (BIP), later known as the Maquiladora Program. The purpose of the BIP was to promote export-led industrialization in northern Mexico, encouraging foreign investment in Mexican maquiladoras. Corollary objectives included the creation of employment and increasing the income of the border population to foment a stronger local economy. The pillars of the BIP were proximity to the United States; use of favorable articles of the U.S. Tariff Code, which permits firms to import goods manufactured abroad with U.S. components to reenter the United States, paying duty only on the value-added, cheap labor; and a Mexican government friendly to investors. Campos Salas was quoted in the Wall Street Journal (on May 25, 1976) as saying, “Our idea is to offer free enterprise an alternative to Hong Kong, Japan, and Puerto Rico” (Bustamante 1983, p. 233). This translated into tax incentives for foreign firms, lax enforcement of environmental laws, and a blind eye to the breaking of labor laws.

Initially, maquiladora enterprises were allowed to settle in a 20-kilometer strip along the Mexican border. After four years, however, Mexican government officials were disappointed with the results. Two important objectives of the program had been: (1) having foreign firms make use of Mexican products and firms (known as linkages with the local economy), and (2) the transfer of technology and know-how to Mexican managers and firms. Neither goal was being met. In addition, maquiladoras experienced high turnover rates, as workers frequently changed jobs, seeking incentives and bonuses to complement low wages. As a result, in 1972, the Mexican government expanded the zone to include all of Mexico. To encourage further growth, the Mexican government provided additional incentives to foreign firms, including lowering the minimum wage in the interior of the country, easing the ability of foreign firms to form joint ventures with Mexican corporations, and, after 1983, granting maquiladoras the opportunity to sell up to 40 percent of their products in Mexico.

At the beginning of the BIP, United States companies trickled across the border. By the late 1970s, however, transnational corporations had taken over the border economy. Since the 1980s, maquiladoras have been the engine driving the Mexican economy, providing more than 1,200,000 jobs.

**EVOLUTION OF THE MAQUILADORA PROGRAM**

Most scholars of Mexican development agree that the Maquiladora Program has progressed through four stages or generations. Jorge Carrillo, Alfredo Hualde, and Cirila Quintero Ramírez denote these as the stages of inception, growth, consolidation, and crisis. During the inception stage (1965–1982), the border region truly operated as an industrial enclave. Under the program’s special directives, products were assembled solely for export. The rest of the country was ruled by import-substitution industrialization, which levied high tariffs to discourage imports and promoted production for the national market.

Most of the firms that participated in the program’s first stage were labor-intensive operations seeking cheap labor. However, the jobs created did not go to the male agricultural workers laid off in 1964 by the termination of the Bracero Program. Managers preferred to hire young women, creating a labor force segregated by age and sex. In 1974, 80 percent of the maquiladora labor force was female. Younger women, between the ages of sixteen and twenty-four, were more likely to work in electronics assembly, while older women tended to work in the lower paying textile and garment industry (see Fernández-Kelly 1983).

Women were the cheapest source of labor available, and they were thus the preferred workers in Mexico (as they had been in the export processing zones of East Asia). Lower wages were justified through the “feminization” of assembly work. That is, assembly was designated as “unskilled” work, and women workers were held to have traditionally feminine skills (such as knowing how to sew and embroider), which were considered useful for such employment. Managers construed women as being “docile, undemanding, nimble-fingered, and uninterested in participating in unions” (Sklar 1993, pp. 171–172). Crucial in this framing was employers’ desire that women not demand higher wages. Moreover, although high percentages of women were the primary or sole providers for their families, they were paid lower wages than their male counterparts. Maquiladora management treated women as supplemental earners deserving of lower wages.

The second stage of growth (1983–1994) was marked by changes in three main areas: (1) There was a shift to export-oriented industrialization, (2) there was an increased participation of men in the labor force, and (3) there was a movement of firms toward the interior of Mexico. Mexico’s inability to pay its foreign debt in 1982 signaled the end of import-substitution industrialization and the opening of Mexican markets to foreign goods and production. Export production was promoted as a crucial means of earning needed foreign exchange to pay the debt and fulfilling International Monetary Fund (IMF) loan deferralment agreements. The Maquiladora Program blossomed, assisted by changes in regulations—such as the ability to sell 40 percent of production within the newly opened Mexican markets and the devaluation of the peso. With the devaluation of the peso, foreign companies’ dollars stretched further, while national firms, who earned
pesos, struggled to compete as inputs, wages, and overhead costs increased overnight.

The ensuing economic crisis resulted in increased unemployment. Under these conditions, men’s participation in the maquiladora labor force increased from 20 to 40 percent. This change did not signal an improvement in working conditions, but rather the precariousness of workers’ situation. There was, however, a continued gender segregation of employment. A significant number of the new firms that settled in Mexico during this second stage were capital-intensive automobile and auto-parts maquiladoras. Because this was considered skilled work, men were preferred to women. These transplants, mostly from the United States, used a combination of old machinery, new computerized equipment, and selective implementation of flexible production techniques, such as teamwork, Just-in-Time (JIT) production, and Total Quality Management (TQM). However, they differed from the U.S. auto industry in a number of key ways. In particular, the selective adoption of work innovations was combined with low wages and heavy control of workers. Lastly, responding to high turnover rates and wages in the border region, there was a slight shift of firms to the interior of Mexico.

The third stage of consolidation (1995–2000) followed Mexico’s signing of the North American Free Trade Agreement (NAFTA). Important changes in this stage included a strengthening of the Maquiladora Program, the rise of the “third generation maquila,” and the geographical segmentation of firms. In effect, NAFTA regulations closely followed the Maquiladora Program tax regime, thus increasing the number of national and foreign firms taking advantage of these terms. Yet because of this similarity, the Maquiladora Program was slated to end in the year 2001. This would have ended the most important advantage of the maquiladoras, a 4 percent tax exemption on wages. In the end, however, the program was extended until 2007 due to the political clout of its lobby association. The future of the program continues to be debated at the highest levels of government.

NAFTA allowed U.S. and Canadian companies to move greater portions of their production processes (not only assembly, as previously allowed) to Mexico. In the garment industry, for example, this meant that design, cut, laundry, and trim operations could move south. New regulations also translated into a large number of Asian and some European firms moving to Mexico in order to take advantage of the all-important U.S. market. The number of firms joining the Maquiladora Program was also greatly enhanced by the devaluation of the peso that followed the signing of NAFTA, which cut wages again. However, wages in maquiladoras were now compared to those in East Asia, among the lowest in the world, and not those of the interior of the country.

The consolidation of maquiladoras was also related to geographical segmentation. Participation and competition in international markets drew more firms to Mexico based on low wages and geographical proximity to United States. Thus, the more labor-intensive firms seeking the lowest wages and costs of production (such as garments, footwear, and toy production) moved south, with the more capital-intensive sectors (electronic, automobile, and auto parts) remaining in the north of Mexico.

In the stage of consolidation, third-generation maquilas grew—those that moved beyond assembly to become highly productive, innovative, world-class firms. While most scholars agree these third-generation maquilas exist, there is great debate as to how widespread and complete the process of industrial upgrading has been. On the one hand, there has been enhanced participation of Mexican engineers and technicians, a crucial element of organizational learning. However, organizational innovations have occurred in only a few large automobile and auto-parts firms. Moreover, these innovations continue to be implemented selectively and in conjunction with low wages, worker control, and union marginalization, instead of the high wages and worker autonomy envisioned in the management philosophies. The result has been a hybrid system of greater productivity through the intensification of work. The majority of maquiladoras remain labor-intensive assemblers with a strong gender division of labor and little possibility for promotion.

The last stage in the development of the Maquiladora Program (2001–2006) was marked by the crisis brought about by the 2001 U.S. recession. Over 80 percent of Mexican production was destined for the U.S. market, so the U.S. recession sent shock waves throughout Mexico. All types of production facilities, including the important maquiladora industrial sector, saw a sharp decline in output and revenues. Many firms either shut down or moved to lower-wage countries, such those in East Asia and Central America, leaving the maquiladora sector in crisis.

**GAUGING THE MAQUILADORA PROGRAM’S SUCCESS**

In evaluating the performance of the Maquiladora Program, it is evident that the goal of development has not been completely fulfilled. The articulation of the local economy (through raw materials, components, and services) to maquiladora export production has been minimal with less than 3 percent of product components being from Mexico (see Carrillo, Hualde, and Quintero Ramirez 2005). Other than in the small number of third-generation maquilas, it is impossible to speak of technology transfer per se, but rather of technology relocation, since most of the technology used in maquiladoras is obsolete. However, in a smaller number of companies where...
advanced technology is used, the number of Mexican technicians and skilled workers has increased.

Not only has the Maquiladora Program not solved the problem of male unemployment caused by the termination of the Bracero Program, it has accentuated it. Women have been drawn to the border region by employment in the maquiladoras, while men have remained mostly unemployed. Border infrastructure has been pressed to the maximum, as cities and towns have spread into the countryside without public services. Moreover, maquiladoras have routinely disposed of toxic waste by either dumping it into public canals that pass through worker communities or by abandoning drums of waste in the desert. One study found that 60 percent of maquilas did not return toxic wastes to the United States, as required by maquiladora regulations (see León Islas 2004). While the program did create an economic boom, with the maquiladora industry bringing in the second-largest amount of revenue for Mexico after oil, it has also exacerbated social inequalities and created ecological disasters along much of the border.

MARCUSE, HERBERT
1898–1979

Herbert Marcuse was a German American social theorist and activist who gained prominence in the 1960s as “the father of the New Left.” Born in Berlin to a prosperous Jewish family, Marcuse served in the German army during World War I and then studied in Berlin and Freiburg from 1919 to 1922. After working as a bookseller in Berlin, Marcuse returned to Freiburg in 1929 to study philosophy with Martin Heidegger. Although he was enamored with Heidegger’s thought, he was deeply dismayed by his teacher’s political affiliation with the Nazis. Though his habilitation, Hegel’s Ontology and the Theory of Historicity (1932), was not accepted because of the rising influence of nazism, Marcuse joined the Frankfurt Institute for Social Research in 1933 and became associated with the neo-Marxist Frankfurt school of critical social theory. In 1934 Marcuse fled Nazi Germany and relocated to Columbia University in New York, receiving U.S. citizenship in 1940. He published Reason and Revolution (1941), which established him as an insightful interpreter of the Hegelian-Marxian tradition of dialectical thinking.

Wanting to aid the war effort against the Nazis, Marcuse joined the Office of Strategic Services as an intelligence analyst in 1943. After the war he worked for the State Department until he returned to academia in 1952 and eventually landed a position at Brandeis, where he taught from 1954 to 1965. In 1955 he published Eros and Civilization, which argues, contrary to Freud, that civilization is not inevitably repressive, but that the unconscious harbors an instinctual drive toward happiness and freedom that is evident in works of art and other creative cultural products. While a “basic repression” of drives is necessary for civilization, Marcuse criticizes contemporary society’s “surplus repression,” especially its exploitative economic organization and unnecessary restriction of sexuality. He outlines an alternative form of social organization in which labor is non-alienated and sexuality is free and open.

In 1964 Marcuse published his most influential work, One-Dimensional Man, which argues that the technology and consumerism of advanced industrial society enables it to eliminate social critique and conflict by assimilating traditional voices of dissent, for example, the voice of the working class. The result is “one-dimensional man,” who cannot think critically about society because it integrates him by continually creating and satisfying “false needs.” Genuine social critique must therefore come from nonintegrated, socially marginalized voices. Marcuse’s supplemental essay, “Repressive Tolerance” (1965), argues that the liberal conception of “tolerance” blunts social critique by demanding tolerance for oppressive speech. He insists upon a discriminating tolerance that prevents certain forms of intolerance from being voiced. Although

criticized by Marxists, *One-Dimensional Man* was a seminal work of 1960s radical thought, and Marcuse began publishing articles, giving lectures, and advising student protest groups all over the world. He influenced such activists as Abbie Hoffman and Angela Davis, who was his student at Brandeis.

Marcuse died on a lecture tour in Starnberg, West Germany. Although his work has been criticized for its lack of empirical analysis, his provocative blend of Marxism and libertarian socialism has inspired much political activism and social critique.

**MARGINAL PRINCIPLE**

**MARGINAL PRODUCTIVITY**

A dominant theme in both the explication and legitimization of a market economy is that if individuals work hard and effectively, they will be appropriately rewarded. Typically understood as the Protestant ethic, the theme provides moral approval for hard work and asset accumulation, even though the terms *hard work, effectively, and appropriately* require technical specification and thereby a narrower meaning than the theme seems to offer at first glance. The moral injunction is transformed when translated into economic theory.

The foremost attempt to do so was by John Bates Clark (1847–1938) in the late nineteenth century. His ethical marginal productivity theory was an attempt to prove mathematically that people receive what they produce. Correctly formulated, the theory says something much less than that: namely, that the wage rate is only an element in an equilibrium equation and not a uniquely causal factor; indeed, that marginal productivity explains only the demand for labor and not the wage rate. The hold of the Protestant ethic is such that even though economists understand the more limited significance of marginal productivity, an inevitable tendency is for some economists to revert to Clark's ethical formulation.

That the marginal productivity theory is only a theory of the demand for labor is easily shown. Assuming (eventual) diminishing returns, the marginal product curve for a particular occupation slopes downward to the right. The wage rate is a function of the demand and supply of labor. The marginal product curve represents the demand for labor for the firm: As the wage rate falls, employers will hire more workers, and vice versa. The summation of the individual firms' marginal product curves yields the market-demand curve for labor. It, together with the labor-supply curve, determines the wage rate. In equilibrium, the intersection of the labor-demand and labor-supply curves will yield the amount of labor hired and the wage rate at which they are hired. The marginal productivity curve enters only into the determination of the labor-demand curve; to determine the wage rate (and employment) one must introduce the labor-supply curve. If, in a particular occupation, the supply of labor shifts to the right, there will be greater employment at a lower wage rate—even though workers are working as hard as before.

Another way of looking at the foregoing is to consider the downward-sloping curve as the value of the marginal product, constructed thusly: The marginal physical product, itself a result of technology, is the immediate cause of the downward slope; the marginal physical product must be multiplied by the price of the product, which is a function of the demand and supply of the product, all of which is separate from or external to the demand for labor. Workers may work as hard as they can, but at best this will only raise slightly the value of the marginal product curve; much more important is technology and the product price. The wage rate is governed largely by nonethical factors.

So, far from proving that people receive (the value of) what they produce, the theory, using the conventional assumptions, proves a tendency toward equal wages. Assume three occupations, each with its respective, negatively inclined marginal productivity curve. Let the three curves start at any three points on the vertical marginal
product axis (employment is on the horizontal axis) and let them decline at different rates. The language, “one occupation is more productive than another,” is predicated neither on one curve starting higher than another on the vertical axis, nor on one curve declining less rapidly than the other. It asserts something stronger, something that is analytically false. Assume further a labor-supply curve for each marginal productivity curve; their three respective intersections yield three wage rates, one for each occupation. The conventional assumptions are competition and labor mobility. Labor in the lowest-wage occupations will move to the higher-paying ones. The labor-supply curve shifts to the left in the formerly low-wage occupation, thereby raising the wage; and vice versa in the formerly high-wage occupations. The process, under the postulated static conditions, continues in principle until the same wage rate prevails in all three industries. The theory produces the result, not that one industry has higher wages because it is more productive than another(s), but that there is a tendency toward equal wages. That the tendency is not reached is due to immobility of labor, noncompetitive conditions, wages as not the only remuneration in a job, and evolutionary and dynamic changes in technology, tastes, and so on.

At any rate, marginal productivity theory is only a theory of the demand for labor and is itself dependent in part on technology and on the demand (relative to the supply) of the product of labor. Other marginalist formulations, with the exception of marginal utility as a theory of value, have not been given ethical status: marginal cost, marginal disutility, marginal efficiency of capital or of investment, marginal propensities to consume and to save, marginal rate of substitution, marginal tax rate, marginal revenue, marginal utility of money, and marginal rate of transformation are important and nonethical categories. So too is the marginal productivity theory as a theory of the demand for labor and employment of labor; it is, however, neither a theory of wages nor the Protestant ethic in economic garment.

MARGINALISM
Marginalism is one of two types of approaches to studying economic and political processes. Each is both a technique of analysis and a view of how both individual economic agents and the economy as a whole function in reacting to change and in causing change, and therefore policy. Marginalism, or incrementalism, gives effect to the methodological individualist perceptions that the meaning of human action is best comprehended at the level of individuals, that change takes place along various margins and not in totals, that decision making/policy is made in a composite manner, as the sum of the results of independent but interacting agents and institutions.

The system comprising all of such agents and institutions moves as a result of marginal adjustments to changes originating within and outside the domain of each. Government, for example, is no single decisional unit; decision making is incrementally developed by a multiplicity of agencies. Systems analysis, on the other hand, gives effect to the methodological collectivist perception that the meaning of any marginal adjustment, agent or institution is a function of the total system of which it is a part. Systems analysis thus facilitates the study of the totality of interacting agents and institutions, therefore of group processes, and how agents and institutions generate and respond to large-scale social forces, problems, and so on. The systems approach to policymaking centers on the study of the economic and political structures and processes within which individual behavior takes place, just as the incrementalist or marginalist approach focuses on the individual behavior putatively independent of systemic structures, processes, and forces. Uniting the two types of approach enables the combined study of the impacts of system upon individuals and of individuals upon system. Moreover, no single mode exists for modeling either parts or wholes, incremental or systemic change. The variety of schools of thought operating in each approach is enormous; and the range of models runs from the single individual to the world system.

Marginalism gives effect to important aspects of change. One aspect is that a change in a variable is not likely to be a change in its totality; that is, in all of it, but a small increase or a small decrease here and/or there, along one margin but not another. For example, a typical change of tastes does not involve now buying fish and no
longer buying pork, but a little more of one and a little less of the other. The change is said to take place at the margin. Another aspect is the impact of a change in one variable at its margin on another variable at its margin. The increase or decrease in purchases of fish may lead to a change in employment in the same direction, and vice versa for pork. The concept of elasticity, for example, relates proportionate changes in quantity to proportionate changes in price or income. A change in aggregate consumption spending will change income in the same direction and may also change investment in the same direction; but not every element comprising the total need change.

Another aspect of marginalism has to do with the tendency of an economy, or parts of it, to adjust so as to reach equilibrium. When consumption increases, leading to an increase in income, consumption further increases, though generally by an amount smaller than the initial increase, and investment also increases; eventually the increases in spending diminish to zero, which will be when spending equals income for one period and income equals spending for the next period; the economy is in equilibrium. As for that increase in investment, the increase in consumption and, with it, income tend to increase the expected rate of profit (marginal efficiency of capital, or MEC) not on all investment but on new investment; that is, investment at the margin; in the example, investment increases as the MEC increases relative to the interest rate, a proxy for alternative uses of money.

Still another aspect of marginalism is its use in optimization. If one defines optimization as when benefit equals cost, then an individual will optimize a line of expenditure at the point of purchase when the additional benefit of an increase in spending equals the cost so that there is no incentive to change spending. A firm will optimize its level of production when the marginal cost of a level of production equals the marginal revenue derived from its sale and when the marginal revenues of different periods and in different markets are equal. An agent is in both equimarginal equilibrium and optimization, when the last dollar spent on each line of spending equals the benefit derived from it, so there is no incentive to change the pattern of spending, given the pattern of tastes. In this simple model, equilibrium and optimization coincide. But, many production processes have increasing returns (marginal cost of another physical unit decreasing). If the good is priced equal to its marginal cost, the total production costs cannot be recovered. Pricing necessarily is an institutional matter of industry cost accounting and other conventions.

HISTORICAL PERSPECTIVE
Marginal analysis in economics originated in two initial forms. The English economist David Ricardo’s theory of rent involved decreasing marginal returns in the form of food from additional increases in inputs so that rent was a differential. The returns are still positive, but decreasing, until they reach zero, eliciting no further increases in inputs. In the English jurist and philosopher Jeremy Bentham’s utilitarianism, an activity is characterized by pain and pleasure, such that an activity will be conducted up so long as the pleasure exceeds the pain (perceived benefits are greater than perceived costs), to the point that the two are equal in magnitude. Whereas Ricardo’s theory involves physical inputs and outputs, Bentham’s theory involves subjective feelings of pain and pleasure.

In the late nineteenth century, albeit with many precursors, several economists used marginalism to construct a theory of value different from cost of production. In their view, the value of anything that is bought and sold is at the point where the marginal (last) buyer and seller agree as to the price of purchase and sale. The buyer derives marginal utility from additional acquisitions of the item. The level of marginal utility decreases as more is acquired. Tracking falling marginal utility is falling demand: Because marginal utility is decreasing, the individual buyer will purchase more only at lower prices. Sellers will sell more only if they receive more, due to increasing costs. This is the subjectivist, or Austrian, theory of value in which value is a function of scarcity, as opportunity cost meets subjective demands in the market.

All aspects of marginalist change have proven to be useful either as conjectural explanation, actual explanation, and/or a tool of analysis of how changes in variables occur and their consequences. In many interesting and important respects, the world changes at the margin.

LIMITATIONS
Marginalism, like all concepts and theories in economics, has its limits. One class of limits has to do with the identification of a margin. If one is going to make marginal comparisons, the arrays of margins must be specified. In some respects this is a matter of the physical monetary activity itself. But in other respects it depends on subjective identifications of the lines along which marginal change will be measured. This will depend in part on how firms and households are organized, on the cost accounting conventions adopted by firms and how they are applied, on legal requirements, and so on. The analysis of consumption usually centers on particular commodities or groups of commodities and may include attention to marginal adjustments between complementary goods and between substitutable goods. The analysis of production, undertaken by the typical multi-product firm, is more complicated. Here the assignment of costs between fixed and variable costs can take place along a variety of different identifications of margins and with numbers further
influenced by the identification of products and product groups and of block levels of production, instead of single units, in the construction of cost accounting. For nonrival goods, marginal cost of another user is equal to zero. If users are to be charged the cost of the unit they use, some could pay nothing, while others pay some share of the fixed cost of production. Who is designated the marginal user is an institutional matter. Thus, if marginal productivity is the incremental increase (decrease) in total output associated with an increase (decrease) in input by one unit (which may be a block of units), the calculation is dependent on the definitions of product line, input, output, and margin.

Another class of limits involves what some economists perceive to be a superficial rendering of human activity. The question is whether people act as they are portrayed in theory, whether the maximizing or optimizing behavior is more complex than, perhaps even different from, that described in marginalist accounts, whether tastes are given or stable, and so on.

A different class of limits involves the larger system of things in which change—marginal change—takes place. If people make marginal adjustments in their buying and selling and other economic activity, the question involved is, in part, what is the market in which this takes place and how is it formed. Markets are created as firms and governments exercise strategic behavior and attempt to form and structure markets to accomplish their goals. Beyond markets alone, the larger system involves the overall structure of power, the legal-economic nexus, the set of macroeconomic policies pursued by governments, and so on, in which marginal adjustments take place and have effects.

Closely related limitations derive from the specification of the unit of analysis. The unit may be a representative firm, a particular industry, or an element of a particular country or of a particular region, as well as the world system. These and other limits apply to both marginal and systems analysis.

Also closely related is the evolutionary dynamics of the larger economic system, a process of change which manifests in changes at the margin but also, and more importantly, swamps marginal adjustments. Further limitations are imposed by theories centering on asymmetric information, expectations, uncertainty, strategic behavior, corporate goal formation, bounded information, and so on. In practice, the various strengths and limits are trumped by the research interests of particular economists and their respective schools of thought.

MARGINALIZATION
Marginalization comprises those processes by which individuals and groups are ignored or relegated to the sidelines of political debate, social negotiation, and economic bargaining—and kept there. Homelessness, age, language, employment status, skill, race, and religion are some criteria historically used to marginalize. Marginalized groups tend to overlap; groups excluded in one arena, say in political life, tend to be excluded in other arenas, say in economic status. Concern with marginalization is relatively recent. As the advance of democratization and citizenship swell the ranks of those “included” in the social order, the plight of those with limited access to the franchise and without rights or at least enforceable claims to rights becomes problematic.

Our discussion focuses on two main issues. First, what are marginalizing processes and how do they operate? Second, why are so many of the same groups—women, ethnic groups, religious minorities—marginalized in a variety of situations and institutions? Major approaches to marginalization are represented by neoclassical economics, Marxism, social exclusion theory, and recent research that develops social exclusion theory findings.

Neoclassical economists trace marginalization to individual character flaws or to cultural resistance to individualism. Their explanations of poverty stress the notion of the *residuum*, defined as those “limp in both body and mind.” This residuum—the term was made famous by the
Marital Conflict

Cambridge economist, Alfred Marshall—will only work when forced to do so. Generous social policies encourage its members to stay out of the labor force. To explain why some groups are found disproportionately in the residuum, economists sometimes cite the presence of a “culture of poverty,” which although adapted to alleviate the worst effects of poverty in fact reinforces it.

In contrast, Marxists see marginalization as a structural phenomenon endemic to capitalism. For Marx, the “reserve army of the proletariat,” a pool of unemployed or partially unemployed laborers, is used by employers to lower wages. Together with déclassé elements, the most impoverished elements from the “reserve army” form the bases for the lumpenproletariat—in Marx’s time, a motley conglomeration of beggars, discharged soldiers, prostitutes, and vagabonds. Marx also noted the presence of ethnic minorities, such as the Irish, in the “reserve army.” He attributed the composition of the reserve army of labor and thus the lumpenproletariat to capitalist efforts to divide the working class along ethnic lines.

Although strongly influenced by Marxism, contemporary social exclusion theory stresses the importance of social networks and symbolic boundaries. Studying the economic recovery of the late 1970s, French sociologists noted that some groups—particularly migrants and youth—benefited relatively little from renewed growth. They concluded that sustained unemployment leads to poverty, which in turn leads to social isolation, including the breakup of families and the financial inability to fully participate in popular culture. Shorn of kin ties and cultural associations, the unemployed have difficulty finding a job and eventually become unemployable.

Current research has led to modifications of social exclusion theory. States and kin networks can play a significant role in moderating the effects of prolonged unemployment. Generous Dutch and Danish welfare states keep the unemployed out of poverty. In Italy and Spain the tendency of all unmarried adult children, including unemployed adult children, to remain in households with members who have ties to labor markets moderates social isolation. Less generous welfare states and the relatively early departure of adult children from households leaves the unemployed in France, Germany, and the United Kingdom especially susceptible to social isolation. Everywhere, immigrant workers, who do not receive the full benefits of the welfare state and whose families are often not integrated into job markets, remain marginalized.

Recent work by American sociologist Charles Tilly further stresses the importance of economic structures and social networks to marginalization. For Tilly, capitalist control of jobs combined with included groups’ monopolization of job niches help explain why adult, native, white men are privileged in many different hierarchies, whereas nonadult, migrant, nonwhite women are invariably among the excluded. He emphasizes that new job hierarchies within capitalist industry tend to be filled according to already existing social distinctions; employers use old distinctions to justify and buttress new workplace distinctions and maintain harmony by endorsing distinctions that already divide the labor force. In so doing, employers and included groups perpetuate existing social distinctions and reinforce them, creating durable inequality.

Increasingly, modern interpretations stress marginalization’s collective character and the role of the state, elites, and entrenched groups in determining who is marginalized. But wherever it occurs, marginalization seldom begins afresh. Institutions typically fill new job hierarchies in line with existing social ranks. Groups marginalized in the past have the best chance of being marginalized in the future.

**MARITAL CONFLICT**

In marriage, conflict occurs when the needs and desires of spouses diverge and are thus incompatible. Because spouses interact with each other regarding a number of issues important to their marriage over time, it is inevitable that conflict will occur to at least some degree in every marriage. It is not the existence of conflict in marriage per se that is detrimental to marital satisfaction or stability, but how spouses manage conflict when it occurs.
Conflicts can be settled positively through discussion, but in some cases may result in the escalation of arguing without resolution, or with each spouse ignoring the area of conflict in an attempt to prevent negative marital interactions. The quality of the marriage suffers when conflicts remain unresolved, and in some marriages the inability to successfully manage conflict can lead to physical abuse, sometimes with severe consequences. Understanding the causes and consequences of marital conflict has been the target of a growing body of empirical research, and the results of this research have been useful in developing therapeutic programs aimed at assisting spouses to manage conflict in a positive manner.

One influential model created by Caryl Rusbult and her colleagues to explain how spouses manage marital conflict is called the exit-voice-loyalty-neglect model (Rusbult and Zembrodt 1983). This model stipulates that spouses can respond to conflict in a positive or negative fashion, and in either an active or passive manner. Walking away from a partner during a conflict (exit), for example, reflects an active/negative way to deal with conflict, whereas ignoring the negative event (neglect) reflects a passive/negative way to deal with conflict. By contrast, openly discussing the conflict and attempting to resolve it (voice) reflects an active/positive way to deal with conflict, whereas hoping that the partner will work alone to solve the problem (loyalty) reflects a passive/positive manner of conflict resolution. In general, voice offers the best opportunity for resolving conflict, while the other options tend to prolong the conflict and erode marital quality.

A second influential model of understanding how spouses manage marital conflict has been developed by John Gottman (1994) over several years. In Gottman's original research, married couples that had reported being very happy or very unhappy with their marriage were asked to discuss areas of conflict in their marriage while being videotaped. Through careful observation of these interactions, it was found that unhappy spouses tended to frequently criticize each other, respond defensively to their partners' comments, treat their partners with contempt, and emotionally withdraw from the discussion. Gottman also found that the more spouses engaged in these four types of behaviors while managing conflicts, the more likely they were to experience declines in marital satisfaction and to eventually divorce.

When faced with marital conflict, certain people are more likely than others to engage in negative interpersonal behaviors. For instance, some people tend to be very anxious about how much their romantic partners love them, fearing that their partners may eventually abandon the relationship. When relationship conflicts occur, these anxious individuals are more likely to become very upset and to believe that their partners will leave them (Campbell, Simpson, Boldry, and Kashy 2005). Also, people that chronically feel less loved by their partners behave more negatively toward their partners in the face of marital conflict (Murray, Bellavia, Rose, and Griffin 2003). Ironically, although these people fear the loss of their spouse and relationship, when conflicts arise, they tend to behave in ways that have been shown to destabilize marriages.

IMPACT ON HEALTH

The inability to successfully manage conflict in marriage is also linked with declines in physical well-being. Research in the late twentieth century revealed that marital disagreement is related to increased blood pressure and heart rate, as well as with alterations in immune functioning. For instance, in a 1998 study of 93 newlywed couples, Janice Kiecolt-Glaser and colleagues found that hostile interactions observed while couples attempted to resolve a relationship conflict were associated with increased levels of epinephrine (adrenaline), norepinephrine, and growth hormone, as well as greater immunological change over the subsequent twenty-four hours. This pattern of results was replicated in a sample of older couples who had been married an average of forty-two years. Therefore, because stressful interpersonal events can result in immunosuppression, which leaves people more vulnerable to a variety of illnesses, couples that are not effective at managing marital disagreement expose themselves to increased physiological stress over time, which leaves them vulnerable to health problems.

In a 1993 article, Craig Ewart finds that the presence or absence of negative behaviors directed toward spouses while discussing relationship conflicts is more responsible for physiological changes than are positive behaviors. For example, hostile marital interactions produced significant increases in blood pressure among patients with hypertension, whereas neither positive nor neutral behaviors were associated with change. Kiecolt-Glaser and colleagues also found that negative, but not positive, behaviors were related to decreases in immune functioning in both short- and long-term marriages. Therefore, responding to marital conflicts with negative interpersonal behaviors is particularly bad for the stability of the marriage and for one's physical health.

MARITAL THERAPY

Therapeutic approaches to marital therapy have been greatly influenced by research on conflict resolution in marriage. Overall, it is agreed that therapy is most effective when both spouses participate. Some therapeutic approaches focus directly on altering the behavior of spouses during conflicts. Spouses are taught to identify their negative interpersonal behaviors during conflict, to
discontinue the use of these behaviors, and to engage in more positive forms of conflict resolution as suggested by the therapist. Alternatively, other therapeutic approaches assume that unhappiness with the marriage is directly related with negative conflict resolution behaviors, and thus focuses on the reasons why people are unhappy with their marriage.

Therapeutic approaches to marital conflicts operate on the premise that if spouses can understand the source of their marital unhappiness and work to make a better marriage, their behaviors in the face of marital conflicts will naturally improve. Both approaches are somewhat effective for improving conflict management in marriage.

**MARKET CLEARING**

The concept of market clearing related initially to the capability of the aggregate economy to generate sufficient purchasing power to assure that the economy’s aggregate output will find purchasers. When this is the case, the total value of the economy’s output will be exactly equal to the total value of the economy’s purchases. In short, the economy’s aggregate demand will be the equivalent of aggregate supply so that a situation historically termed a glut of output will be nonexistent.

Concern about the possibility of a glut dates (at least) to late-eighteenth-century France, where production was directed by central authority toward luxury products intended for export (for example, tapestries, crystal, velvet) in order to increase the economy’s ability to earn gold via trade. The fear that French purchasing power could become insufficient was quelled by the articulation of a generalization by Jean-Baptiste Say in 1803 that became known as “the Law of Markets.” It maintained that, because the value generated by the process of production simultaneously generates an equivalent flow of factor payments, an insufficiency of purchasing power is impossible because “supply creates its own demand.” The logic of Say’s argument was introduced into England by John Stuart Mill in the mid-nineteenth century and continued to dominate academic thinking until the mid-1930s, as Ingrid Rima notes in her 2001 work. Traditional nineteenth-century thinkers concerned themselves primarily with the problems of value and distribution and the equilibration of competitive markets, although they also understood that monetary expansion could result in inflation. The argument that purchasing power in the aggregate economy might be deficient was largely the province of monetary reformers who were unaware that Say’s Law was predicated on a barter interpretation of the aggregate economy so that money served simply as a convenience to facilitate exchange.

It was not until the depressed 1930s that attention was focused on the linkage between changes in monetary aggregates and changes in real economic activity. John Maynard Keynes wrote his *The General Theory of Employment, Interest, and Money* (1936) to challenge Say’s Law on the ground that it is inapplicable to a monetary production economy: “Say’s Law is not the true law relating the aggregate demand and supply functions” (p. 26), because in a monetary economy the aggregate demand function does not coincide with the aggregate supply function. In particular Keynes maintained that it is the part played by the aggregate demand function that has been overlooked (p. 89). Thus his theory focused on the components of aggregate expenditures, emphasizing the stable relationship between consumption and income and the great instability of investment expenditures in consequence of the inherent uncertainty of the marginal efficiency of capital (Davidson 1972) relative to the rate of interest paid for funds, whether these are borrowed or internally generated (Minsky 1982). The argument that followed was when aggregate effective demand falls short of the economy’s resource capability (given the level of technical knowledge), the demand deficiency is evidenced principally in the involuntary unemployment of some part of its workforce (Keynes 1936;
Weintraub 1966). Thinkers who responded positively to Keynes's argument looked to fiscal policy, that is, reduced tax collections and increased government spending financed via bond sales to increase aggregate spending via the operation of the multiplier, which was expected to enable both commodity and labor markets to clear at a higher income level. The persuasiveness of the theory of aggregate demand culminated in the “Keynesian revolution,” which shifted economists’ perspectives to the behavior of the economy’s macroeconomic magnitudes. The shift underscores the distinction between the market equilibrium of industry demand and supply curves and market clearing in the sense of equivalence of aggregate demand and aggregate supply, in which full employment was shown to be the economy’s normal equilibrium state.

It is perhaps not surprising that the ink of The General Theory was hardly dry before John R. Hicks of Oxford University wrote “Mr. Keynes and the Classics: A Suggested Reinterpretation” (1937), in which he maintained that the criticism of indeterminacy that Keynes made against the classical theory of interest was equally the fault of his own liquidity preference theory. Hicks's reinterpretation suggested that by joining liquidity preference to abstinence theory, which he represented in terms of two new curves, the IS and the LM curves, it can be shown that savings are a function of both income and the interest rate. The intersection of the IS curve and the LM curve, which brings together the four variables of the interest rate problem, the savings function, the investment function, the system’s monetary stock, and the liquidity preference function, will make the interest rate determinant. Thus Hicks and the Harvard professor Alvin Harvey Hansen (1953) integrated the general equilibrium approach introduced by Leon Walras in the 1870s to demonstrate mathematically that all markets are interdependent and simultaneously able to clear goods and factor markets via the guidance of an auctioneer through whom participants “re-contracted” until mutually satisfactory trades could be consummated. Thus began a counterrevolution against Keynes (sometimes called neo-Walrasianism) that reasserted the market clearing capability of an economy characterized by flexible wages and prices (Patinkin 1956).

In a 1956 model that also incorporated the labor market, Don Patinkin maintained that Keynes did not adequately recognize the significance of price changes on the real value (that is, the purchasing power) of monetary balances and wealth as a mechanism for restoring commodity, bond, and labor market equilibriums with full employment. In effect the integration of Walrasian foundations onto Keynes’s model, whose foundation is Marshallian, undermined the Keynesian revolution.

It was to address neo-Walrasianism challenges to Keynes’s credibility that Robert Clower (1965) and Axel Leijonhufvud (1967) undertook reinterpretations of Keynes’s General Theory as a disequilibrium problem attributable to information and coordination failures. They argued that markets clear when potential traders successfully make the adjustments needed for market clearing instead of lagging behind. The theoretical contributions of Clower and others underscored the inadequacy of the micro-foundations inherent in the so-called “Keynesian” framework. Their efforts encouraged an increasingly elaborate micro-approach to rationalize sticky wages and prices in efficiency terms (Barro and Grossman 1976). The essential research focus for many Keynesian economists thus became to identify the reasons for ongoing wage and price rigidities that impede market clearing and to explain the successes and failures of coordination or its absence (Weintraub 1979).

MARKET CLEARINGHOUSE

A clearinghouse is a third-party establishment that operates with stock exchanges to clear trades, collect and main-
tain margin monies, regulate delivery, and report trading data. All trades on an exchange go through the clearinghouse. Three million contracts trade each day on the Chicago Mercantile Exchange, and 1.5 billion shares change hands each day on the New York Stock Exchange (NYSE). If an exchange clearinghouse were to fail it would trigger a financial meltdown. When the stock market crashed in 1987 the Federal Reserve moved quickly to provide access to liquidity for exchange clearinghouses, and none failed.

The clearinghouse performs two principal functions: (1) accounting; and (2) contract guarantee. Accounting is a necessity, but it can be outsourced. The fundamental economic function of the clearinghouse is the contract guarantee, which makes large-scale anonymous trading feasible.

The accounting function is easy to understand and mechanically hard to complete. The clearinghouse keeps the books. At the end of the trading day (or on rare occasions during the trading day) the clearinghouse requires that traders balance their account. The guarantee function is harder to understand, but it is the reason for the clearinghouse. In any transaction a seller agrees to deliver at a price and a buyer agrees to take delivery at that price. But for transactions separated in time or space, payment and delivery are uncertain. The clearinghouse puts itself in the middle of each transaction. Technically, buyers buy from the clearinghouse and sellers sell to the clearinghouse. If the seller fails to deliver, he or she defaults to the clearinghouse. The clearinghouse delivers to the buyer. Traders on organized exchanges do not concern themselves with the creditworthiness of their trading partner because their trading partner is the clearinghouse.

In over-the-counter markets traders trade directly with other traders—there is no clearinghouse in the middle. In most over-the-counter markets trades take place only among principals (large financial institutions) that know each other very well.

The clearinghouse guarantee exposes the clearinghouse to default risk. Most traders operate on credit. The clearinghouse requires traders to post margins (collateral) on their accounts so that they have an incentive to perform, and if they do not perform the clearinghouse has immediate access to the collateral. Setting the correct margin involves walking a fine line: a margin too high pushes traders off organized exchanges, and a margin too low exposes the clearinghouse to excess risk.

eBay is an Internet auction site that bills itself as “The World’s Online Marketplace.” Traders meet virtually to agree on the terms of a trade for virtually any item. A big problem for eBay is that a few sellers do not deliver and a few buyers do not pay. If potential eBay traders do not have confidence in the performance of their trading partner, then they will not go to eBay for trades, and the exchange dies. eBay works hard to assure traders that their transactions will be consummated.

eBay bought PayPal, an electronic payments system, in 2002. Through PayPal, one can authorize credit card payments or electronic check transfers. PayPal provides eBay with an electronic accounting system, the first function of a clearinghouse. In addition, PayPal has begun to guarantee transactions. If one buys from a PayPal authorized seller using the electronic check payment method, then PayPal guarantees delivery of items that cost less than $1,000. PayPal also guarantees that the seller will receive payment.

In conclusion, exchanges provide an anonymous marketplace for traders in modern economies. Clearinghouses provide the assurance that delivery and payment occurs.

**MARKET CORRECTION**

*Market correction* refers to a temporary reversal of an upward trend in security prices. Market corrections typically involve a drop of between 10 to 20 percent in security prices. Such declines are temporary secondary trends that are exhibited within a larger upward trend in security prices. Every asset class, including stocks, currencies, commodities, and real estate, has been subject to periodic episodes of corrections. History shows that a 20 percent correction occurs once every five years in the stock market.

The phenomenon of a correction can be understood better within a theoretical framework of an equilibrium asset pricing model. The prediction of a multifactor asset pricing model is:

$$\mu = \lambda_0 + B\lambda_K$$

where $\mu$ is a vector of expected returns to $N$ securities, $\lambda_0$ is the risk-free parameter, $B$ is a vector of factor sensitivities, and $\lambda_K$ is a $(K \times 1)$ vector of factor risk premia. The equilibrium model predicts that changes in expected returns occur in response to changes in the risk-free rate,
or in factor premia. An increase in expected return should lead to a drop in prices, which is, in turn, reflected as a market correction.

Some of these theoretical predictions are upheld by the data. It is now well accepted that most market corrections are preceded by a sharp jump in short-term interest rates. An increase in the risk-free rate of interest is predicted by theory to increase the expected return, and hence to lead to a drop in current prices. Market corrections have also been driven by a decline in earnings momentum. The decline in earnings momentum leads investors to revise downward their expectation of future profitability. This, in turn, leads to a drop in current stock prices.

Revised beliefs about economic conditions, however, only partially explain why corrections occur. In a challenge to rational asset pricing models, fear and greed have been advanced as explanations for market corrections. It is believed that market corrections curb excessive investor optimism, also labeled as greed. Fear of further market declines keeps markets down thereafter. The situation reverses when rational investors step in to exploit the buying opportunity created by price drops. Proponents of this irrational behavior offer the short-lived nature of a typical correction as evidence to bolster their view. The average length of a market correction over the period from 1872 to 2004 has been about twelve months. Security prices return to their precorrection levels after this period and, in fact, continue to trend upward thereafter. Such a reversal is inconsistent with a theoretical asset pricing model since the underlying economic conditions that may warrant a market correction do not experience a similar reversal.

Whatever processes underlie a market correction, investors can expect to experience steep drops in security prices periodically. They should also expect every asset category to experience such corrections. Globalization of financial markets has meant that international markets are also not immune to such corrections. Emerging markets experienced a steep market correction of greater than 20 percent during May to June of 2006. Higher volatility in emerging markets makes them more susceptible to frequent market corrections.

Experienced investors are able to weather market corrections with appropriate risk management strategies, the simplest of which is diversification. Diversification across different asset categories protects an investor from steep drops in any one market. Diversification also imposes the discipline of reallocating a portfolio to restore optimal allocations to beaten down sectors of the market. It is these buying activities that have enabled markets to recover soon after a sharp correction.

MARKET ECONOMY
A market economy is an economic system that allocates scarce resources based on the interaction of market forces of supply and demand. It is an economy that operates by voluntary exchange and is not planned or controlled by a central authority. A market economy, also called a free economy or free enterprise economy, is the conceptual opposite of a command economy, also known as a planned or government-controlled economy, where all goods and services are produced, priced, and distributed under government control. In the twenty-first century a market economy is most often associated with a capitalistic economy.

The market is a process in which individuals interact with one another in pursuit of their separate economic objectives. The basic principle under which the market functions is: If an individual has undisputed ownership of something and wishes to exchange it for another thing that is owned by someone else and the exchange is executed without violence, theft, or deception, then the individual becomes entitled to what the other person was previously entitled and vice-versa. Both parties to an economic transaction in the market benefit from it, provided the transaction is bilaterally voluntary and informed. In this way, through the market process everyone is able to escape coercion at the hands of any one buyer or seller by turning to another. The market prevents one person from interfering with another, allowing a high degree of autonomy. In addition, the society is able to reap the benefits from the division of labor and specialization and function.

The prices that emerge from voluntary transactions, which are motivated by separately self-interested individual behavior, generate a spontaneous order. Many economic theorists argue that these prices coordinate the activity of people in such a way as to make everyone bet-
Market Fundamentals

The market fundamental (or fundamental value) of an asset is the discounted present value of the stream of future cash flows attached to the asset. When asset prices are determined by market fundamentals, the value of the asset depends positively on future expected cash flows and negatively on the discount rate used to obtain the present value. Although some estimates of market fundamentals move together with market values, they tend to exhibit lower volatility. This evidence, especially in the case of the stock market, suggests that asset prices deviate from their fundamental values.

The cash flows obtained by the owner of a stock are the dividends distributed by the firm. Since the source of dividends is the earnings generated by the firm, investors must take into account the factors behind earnings when forming expectations concerning future dividends. The most important factors that determine the evolution of expected earnings are the future profitability of current operations and future investment projects.

The second component of the market fundamental of stocks is the discount rate used to obtain the present value of dividends. Given a fixed stream of cash flows, an increase in expected future returns implies that the market fundamental decreases because the discount rate is higher. Expected returns for individual stocks and for the stock market as a whole are not constant, and different financial and macroeconomic variables contain significant information to forecast returns. This evidence implies that changes in expectations of future returns (i.e., changes in discount rates) can produce fluctuations in market fundamentals. In fact, John Campbell (1991) shows that movements in the aggregate stock market prices are mainly driven by news about future expected returns. However, Tuomo Vuolteenaho (2002) shows that stock returns for individual firms are mainly driven by cash-flow news, and that cash-flow news is largely idiosyncratic, while expected-returns news is common across firms. By a diversification argument, the results of both authors are compatible. Historically, the average real return on the stock market is higher than the real return on treasury bonds. The difference between both returns is denominated as excess return. It is a reward for holding a risky security. Hence, we can decompose the fluctuations in expected returns into changes in the expected return on a treasury bond and the expected excess return. John Campbell and John Ammer (1993) show that stock returns movement can be attributed to news about future excess returns, and that news about the return on a treasury bond has little impact. Therefore the most important component in the discount rate is the excess return. Since it is a reward for risk, the factors that determine its magnitude are

investors’ attitudes toward risk and the risk associated with the stock market. The variables that forecast excess returns are connected to macroeconomic activity. Returns forecasts are high at the bottom of business cycles and low at peaks.

Different valuation ratios have been proposed to anticipate the evolution of stock prices. The most common is the price-earnings ratio, which is computed as the quotient between the price of a stock and its earnings per share. Given the definition of market fundamental, the price-earnings ratio depends positively on future expected earnings growth and negatively on future expected returns. This ratio presents long cycles of approximately thirty years (for the U.S. aggregate stock market during the last century) together with shorter fluctuations. For the aggregate stock market, some authors argue that the price-earnings ratio incorporates significant information to predict future returns for long horizons (more than five years). This conclusion has been criticized mostly from a statistical point of view. John Cochrane (1992) argues in favor of the capacity of the price-dividend ratio to predict returns. The author shows that as the ratio is not constant, it must predict changes in dividend growth or changes in returns. He also provides evidence showing that almost all variation in the ratio is due to changes in returns forecasts.

The market fundamental of a house can be analyzed through similar arguments. It is the expected present value of future housing services. Because the value of housing services is not observable, some authors approximate this magnitude by the rental value of the house. This variable depends on a wide set of factors, such as the characteristics of the rental market or the evolution of the population. Different empirical studies emphasize the importance of the fluctuations in the discount rate in determining housing prices. Further, housing provides collateral services and allows for tax deductions. Intangible services and tax variables may also influence the value of the stock.

There are also other assets where the market fundamental may be hard to define. For instance, the exchange rate is the price of two currencies, and hence the relative price of two assets. Exchange rates may be influenced by the availability of international reserves, balance-of-payments deficits, and monetary and fiscal policies. These macroeconomic aggregates are usually referred to as market fundamentals. Economists build stylized models to evaluate the effects of these market fundamentals.

MARKETS
Several disciplines, among them economics, political economy, philosophy, ethics, and, as of the late twentieth century, sociology, anthropology, and geography, rely on the notion of a market to establish a nexus between those who wish to purchase a commodity and those seeking its sale at a mutually acceptable price or exchange value. While specialists in the latter three fields concern themselves with markets in the sense of trading places observable in the less developed economies of the world, modern economists are principally concerned with an explanation of pricing under different market conditions. For the philosophers of Greece, in particular Aristotle, exchanging an article for money was considered “unnatural.” In *Politics* he observed that there is a double way of using
every article. “There is its wear as a shoe and there is its use as an article of exchange” (I.9, 1977, pp. 39–41). The “natural” use of an article is for consumption, while its exchange for money is an improper or “unnatural” use. Clearly, the distinction the philosophers made between value in use and value in exchange in a market is a reflection of the contempt they had for mercantile activities.

EARLY RELIGIOUS AND POLITICAL VIEWS

The influence of the Greek philosophers on intellectual thought and human behavior was eclipsed by the fall of the Roman Empire in 476 CE. Their teachings were not rediscovered until translations were made from Aramaic sources by early Christian scholars in the twelfth and thirteenth centuries. Church scholars (the Scholastics) reinterpreted Greek ethics and philosophy to meld them with the Catholic Church’s doctrines, including that of the “just price” as the market outcome that results from the moral behavior of both buyers and sellers, so that the resulting exchange value serves the common good. The central role of the “just price” derives from the papal bull *Unam Sanctum* (1302), enunciated by Pope Boniface VIII, which not only reflects the authority of Christian doctrine, but also implies the political priority of the state, vis-à-vis the family and the individual. Throughout the Middle Ages the dominant perspective about human behavior was that it should be guided by the goal of salvation.

By the mid-sixteenth century Church doctrines were challenged by the rise of nation-states and divine-right monarchies in England, France, Spain, and Holland. Their belief was that a nation’s stock of gold was an index of its wealth and power, which led several of their thinkers to a theory of foreign trade that identified a favorable balance of trade (i.e., an export surplus) as the cause of national wealth. Merchant activity in foreign trade was thus accorded social status above artisans and manufacturers, while agricultural labor placed last. Interest in trade also promoted quantitative concepts and techniques, such as William Petty’s *Political Arithmetic* (1690), to explain social phenomena. The logic of explaining prices in terms of the physical costs of producing goods thus replaced the subjective perspective inherent in the medieval notion of just price and its counterpart, the “just wage.” The rise of the European nation state is thus intimately related to the development of political economy, and ultimately of capitalism.

OPTIMISTIC AND PESSIMISTIC APPROACHES

The view of the market that followed in the eighteenth century originated in the Scottish Enlightenment and was envisioned as the outcome of multiple individual choices adapting to evolutionary changes to promote maximum happiness for the greatest number of individuals. This optimistic vision underlies Francis Hutcheson’s (1694–1746) *System of Moral Philosophy* (published posthumously in 1755), whose teachings influenced David Hume’s natural order philosophy, which explored its beneficence to human freedom and happiness that is fully manifested in a market economy. Hume’s work greatly influenced Adam Smith, whose *Theory of Moral Sentiments* (1759) explores the complementarity between sympathy and self interest that is central to the functioning of a market economy: In *The Wealth of Nations* Smith observes, “It is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their self interest” ([1776] 1977 Vol. 1, p. 10). Thus, Smith viewed the functioning of markets as the outcome, on the one hand, of the innate capability of humans to engage in moral behavior socially, while also serving their self interest.

Smith’s starting point in *The Wealth of Nations* (1776) was to link the functioning of the economy to the division of productive labor as the basis for economic progress in raising the economy’s standard of living. Increasing division of productive labor (by which Smith means labor that results in a vendible product), favors the expansion of markets, encouraging still further division of labor, while promoting a larger proportion of productive workers in the population. The market price of every commodity oscillates in accordance with the proportion actually brought to the market. Thus, the market price tends to converge to a price that pays the wages of labor (at their natural or subsistence level, the profits of capitalists (which competition pressures toward zero), and the rent of land (which tends to increase as population growth necessitates the use of inferior soils). The increasing division of labor enhances productivity and thereby ensures economic progress, broadens markets, and enhances the well being of each of the three great social classes: laborers, capitalists, and landlords.

Notwithstanding the optimism inherent in the invisible hand doctrine, the thesis that market wage rates tend toward the subsistence levels anticipated the pessimistic worldview of the nineteenth century that led Thomas Carlyle (1795–1881) to describe political economy as the “dismal science” (*Critical and Miscellaneous Essays* 1849, p. 84). While Smith attributed downward pressure on wages to the relatively greater bargaining power of employers, many who followed him, the English Economist Thomas Robert Malthus among them, attributed the tendency toward subsistence wages to the combined effect of population growth and rising food costs in consequence of diminishing returns. Classical thinkers were thus fully cognizant that the market allocates income shares among
workers, capitalists and landowners, as well as goods among households. These forces led the English economist David Ricardo to offer the theory of comparative advantage to explain the gains inherent in international trade, which encourages improvements in productive technology and international division of labor, which will enhance worker productivity and the rate of profit, and help the working class to participate in the gains from trade.

The advent of the “marginal revolution” led by William Stanley Jevons in England, Carl Menger in Austria, and Leon Walras in Switzerland (who published almost simultaneously in the 1870s), introduced a subjective perspective as an alternate to the classical cost of production view of exchange value, which predicated values on the utilities that consumers placed on their purchase. Because it is their objective to maximize their total utilities, consumers reallocate their commodity holdings until they achieve a set of values that represents an equilibrium state from which no further improvement is possible. This is the vision that led subsequently, principally in the work of Leon Walras (1834–1910) and Vilfred Pareto (1848–1923), who jointly founded the Lausanne School in the twentieth century, that when viewing an economy in its entirety there is a tendency for all of its sectors to move toward simultaneous (i.e., general) supply and demand equilibriums in each of its commodity and factor markets. This is an outcome that lends itself toward representation in a group of simultaneous equations from which Walras demonstrated that it is possible to derive a mathematical solution for market outcomes, given the necessary data. In practice, of course, markets establish actual quantities and prices through the interaction of demand and supply.

**PRINCIPLES OF ECONOMICS**

An alternative to explaining market outcomes exclusively in terms of marginal utility, which built on the mature classical tradition of John Stuart Mill, and which is known as neoclassicism, emerged in England with the publication of Alfred Marshall's *Principles of Economics* (1890). Its distinguishing feature is its eclecticism, which joined marginal utility as underlining the demand side of market behavior (which he pioneered independently of the English economist and logician William Stanley Jevons [1835–1882]), with the classical cost of production explanation of the supply prices of output. By maintaining the interaction of demand (or utility) and supply (or cost or production) in determining prices, Marshall emphasized the central importance of the time periods during which competitive industries are able to make adjustments to consumer demands. In the short run, when inventory has already been produced, costs of production are relatively less important in setting prices than are consumer demands. The short run, during which investment in fixed plant and resources are in place, outputs can be varied by changing inputs of labor and raw material so that costs of production become equally important as demand in establishing prices. In this period the number of firms in an industry becomes expanded or contracted in response to profits or losses, so that in the long run, when all inputs are variable, competitive prices will tend toward equality with the costs of production incurred in response to consumer demands. Thus, Marshall's focus (unlike the French economist Léon Walras's [1834–1910] general equilibrium) for explaining prices was on “short causal chains” of partial equilibrium to explain what happens in commodity and factor markets.

With the publication of Marshall's eighth edition of *Principles of Economics* in 1920, the basic supply and demand framework for conceptualizing market behavior and outcomes, along with the vision of economics as a moral science, was established in the United Kingdom and the United States. The only important addition was the subsequent recognition by scholars Edward Chamberlin and Joan Robinson that the commodities sold in most markets are fundamentally differentiated from competing products via advertising, packaging, design, and sales locales. The latter give individual firms a degree of control over selling prices that renders their markets monopolistically competitive. In other industries, the increasing returns that are inherent in large scale production cause firms to expand so that a few large firms (i.e., oligopolies, many of which are multinational firms) dominate markets in which prices deviate from competitive cost of production prices in consequence of both product differentiation and competition among few (rather than many) large firms. Globalization and electronic communication, along with the apparent widespread political preference for privatization and profit driven decision making, suggests an emerging overlap in the behaviors and outcomes in markets worldwide.

There is, however, an important difference between economies that have become privatized since the decline of communism in 1989 in the former Soviet bloc, and American and Western European capitalism. The transition from collectivism to market-oriented decision making has been accompanied by reductions in output, increased unemployment, and rising prices.

MARKOWITZ, HARRY M. 1927–

Harry Max Markowitz was born in Chicago, Illinois, on August 24, 1927, the only child of Morris and Mildred Markowitz. While he grew up during the Great Depression, his parents, who owned a small grocery store, were more than adequately able to provide for him during some difficult economic times in the United States. During his high school years, Markowitz developed an interest in philosophy that continued throughout his college years. After completion of his bachelor of philosophy degree in 1947, however, Markowitz decided to study economics.

Markowitz was particularly drawn to the “economics of uncertainty” through works by John von Neumann, Oskar Morgenstern, Jacob Marschak, and Leonard J. Savage. He received his MA in 1950 and his PhD in 1954. While at the University of Chicago, Markowitz was selected to join the prestigious Cowles Commission for Research in Economics. Markowitz developed the basic concepts of portfolio theory while working on his doctoral dissertation at the University of Chicago. In his brief autobiography published by the Nobel Foundation, he noted that his basic ideas for portfolio theory came to him while reading John Burr Williams’s Theory of Investment Value (1938). Markowitz introduced modern portfolio theory to the world with his paper “Portfolio Selection,” which appeared in the March 1952 issue of the Journal of Finance. He later published a more extensive explanation of portfolio theory in his book Portfolio Selection: Efficient Diversification of Investments (1959).

Before Markowitz’s research, investors focused on evaluating the risks and rewards of individual securities when creating their portfolios. The goal of portfolio management was to identify individual securities that offered the highest expected return for a given level of risk and then build a portfolio from these securities. Correspondingly, if pharmaceutical company stocks had good risk–reward characteristics, then an investor could infer that creation of a portfolio entirely from these stocks was optimal. Markowitz formalized the intuition, however, that this logic was flawed. Formulating a mathematics of diversification, he asserted that investors should select portfolios based on their overall risk–reward characteristics. From the entire universe of possible portfolios, the ones that optimally balance risk and reward belong to what Markowitz called an efficient frontier of portfolios. Specifically, a portfolio on the efficient frontier is one in which: (1) no additional diversification can decrease the portfolio’s risk for a given expected return, and (2) no additional expected return can be gained without increasing the portfolio’s risk. Markowitz proposed that investors should select portfolios from those that lie on the efficient frontier. This work is considered by many to be the first pioneering contribution in the field of financial economics.

An indirect but significant additional contribution by Markowitz to the theory of financial economics occurred through the use of Markowitz’s portfolio theory as a basis for developing the capital asset pricing model (CAPM). Thus, Markowitz’s work on portfolio theory is regarded by many as establishing financial microanalysis as a prominent research area within economics and finance. Markowitz’s work is also consistent with the Modigliani–Miller theorem, which implies that it is not in the interest of investors for firms to reduce risk through diversification, because investors can achieve diversification through their own portfolio choices.

Markowitz’s work is not without criticism. Many challenge his assumption that rational investors are risk averters. In the world of speculation in financial markets, market bubbles and herd behavior do occur. In these situations, investors often demonstrate behavior of seeking risk or ignoring risk or both. Markowitz’s work is also in conflict with the efficient market hypothesis, which implies that portfolio management is of limited value.

Upon leaving the University of Chicago in the early 1950s, Markowitz concentrated primarily on the application of mathematics and computer methods to problems of business decisions under uncertainty. Markowitz spent ten years on the research staff at the Rand Corporation. He then held various positions with Consolidated Analysis Centers, Inc. (1963–1968), the University of California at Los Angeles (1968–1969), Arbitrage Management Company (1969–1972), and International
Business Machines Corporation’s T. J. Watson Research Center (1974–1983) before becoming a faculty member of Baruch College of the City University of New York in 1982. His most notable work falls in the areas of portfolio theory, sparse matrix techniques, and the SIMSCRIPT programming language. In 1989 he was awarded the von Neumann Prize in Operations Research Theory by the Operations Research Society of America and the Institute of Management Sciences. In 1990 Markowitz shared (with Merton H. Miller and William F. Sharpe) the Nobel Prize for Economics for theories on evaluating stock market risk and reward and on valuing corporate stocks and bonds.

MARKUP PRICING

The term *markup pricing* assumes that a hypothetical firm when setting a price makes it equal to average costs plus some reasonable profit margin that can be expressed as *cost times a markup*. There are different theoretical treatments of markup pricing, however. In the neoclassical theory of monopoly, the law of supply and demand is assumed and the markup is thought to be determined by the elasticity of demand. The post-Keynesian theory, on the other hand, assumes some monopolization of markets due to concentration, entry barriers, and collusion within or across industries and does not consider the law of supply and demand a relevant factor—that is, prices are not thought to respond to disequilibria in supply and demand. The markup is assumed to be determined by the degree of monopoly. Since the 1970s, theories of what is called *dynamic markup pricing* have also been developed.

NEOCLASSICAL THEORY OF MARKUP PRICING

The neoclassical theory assumes the existence of monopolies or monopolistic competition due to differentiated products. In a market for differentiated products, a large number of firms compete by selling similar products but they are not perfect substitutes for one another. A firm confronts certain limitations imposed by the nature of consumer demand—that is, the fact that consumers are more willing to buy products at lower prices than at higher ones. Thus, the firm’s profit-maximization problem can be written as

\[
\max p(y)y - c(y)
\]

where \(p(y)\) is the inverse demand function, and \(c(y)\) the cost function.

The profit-maximizing condition is

\[
p(y)[1 - \frac{1}{|\eta_D|}] = c'(y)
\]

where \(|\eta_D| \equiv |(p/y)(dy/dp)| > 1\) is the elasticity of demand in absolute value. Because consumer demand is inversely related to the price, \(\eta_D\) is never positive. The elasticity of demand must be greater than 1 in absolute value, or the condition is contradictory to nonnegative marginal cost, \(c'(y) \equiv MC > 0\).

Rearranging the above, we obtain

\[
p(y) = \frac{|\eta_D|}{|\eta_D| - 1} MC
\]

or

\[
\frac{p(y) - MC}{p(y)} = 1 - \frac{1}{|\eta_D|}
\]

The left side of the equation indicates the ratio of profit to price, while the right is the so-called Lerner index, which is inversely proportional to the elasticity of demand. The elasticity of demand \(|\eta_D|\) is independently determined by consumer behavior. Hence, assuming that \(|\eta_D| = 4\), we can see from the first formula that the price is equal to marginal costs times 4/3 times the marginal costs. In this theory, markup pricing is, therefore, an attempt by a firm to guess the market’s elasticity of demand. Higher elasticity leads to a price closer to the competitive price.

POST-KEYNESIAN THEORIES OF OLIGOPOLISTIC PRICING

Theories of monopolistic and oligopolistic markets in post-Keynesian economics were developed based on the assumption that concentration, entry barriers, and collusion within or across industries prevent prices from responding to disequilibria in supply and demand. The markup is determined by the degree of the monopoly that gives the firm or entrepreneur the power to increase a price.

\[
\text{MARKUP PRICING}
\]

\[
\text{NEOCLASSICAL THEORY OF MARKUP PRICING}
\]

\[
\text{POST-KEYNESIAN THEORIES OF OLIGOPOLISTIC PRICING}
\]

Kalecki (1971) holds the view that the different markups in different industries are determined by the degree of industrial concentration and that the different markups within one industry are determined by the distribution of power among the firms in the industry. This can be expressed as

\[ p = mu + n\bar{p} \]

where \( n \) is the variable cost, \( \bar{p} \) the weighted average price of all firms in the industry, and \( m > 0 \) and \( 0 < n < 1 \) are coefficients that indicate the firm's position within the industry. The weighted averages, \( m \) and \( n \), which reflect the degree of industrial concentration, determine the average price in the industry and thus the average markup:

\[ \bar{p} = \frac{m}{1-n} u \]

whereby the factor before the \( u \) is the markup.

Target return pricing is a variant of markup pricing that is often found in post-Keynesian economics. Price is set to earn a profit margin that yields a target rate of return on capital at a standard volume of output:

\[ p = ULC^N + UMC^N + \frac{\pi K}{x_N} \]

\[ = (1 + \mu)(ULC^N + UMC^N) \]

where \( \pi \) is the target rate of return on capital, \( K \) the capital stock, \( x_N \) the normal output, \( ULC^N \) and \( UMC^N \) the unit labor and material costs respectively at a normal output, and \( \mu \) the markup factor. The markup over variable cost \( \mu VC = \frac{\pi K}{x_N^N} \) changes either because of changes in the target rate of return or in the capital-output ratio.

Studies by Robert F. Lanzilotti (1958), Wood (1975), and Eichner (1973, 1976, 1980) are concerned particularly with pricing decisions by large corporations. These economists maintain that prices are likely to be set so as to assure the internally generated funds necessary to finance a firm's desired rate of capital expansion:

\[ p = VC + FC + CL \]

where \( VC \) is variable cost, \( FC \) fixed cost, \( CL \) corporate levy (the desired internal funds to finance the investment expenditure), and \( CU^N \) normal capacity utilization. If variable and fixed costs are held constant, the markup is determined by corporate levy, though it may be limited by substitution, the entry of new firms, and government intervention.

Despite the fact that there are several accounts of the markup within post-Keynesian economics, post-Keynesian theories do nonetheless all share an assumption: that prices change primarily due to a change on the cost side (though this is less due to the law of supply and demand than would be the case for neoclassical theorists).

**DYNAMIC MARKUP PRICING**

According to dynamic markup pricing theorists, while firms can decide their own prices and markups, they are nonetheless guided by the need to build up customers in order to expand their future market shares. Firms also have to face competition with a few rivals in the oligopolistic market and threats from potential entrants into the market. Furthermore, customers may leave or switch to other firms. In this sense, the firms have restricted choice since their pricing decisions should be based on considerations of the current and future state of the market. In this dynamic framework, a firm's markup pricing is greatly dependent on other firms.

Economists such as Joe Staten Bain (1956), Sylos-Labini (1969), Franco Modigliani (1958), and David P. Baron (1973) have long argued that price and markup function as barriers to market entry set up by incumbents who wish to deter potential competition. This version of oligopolistic pricing is called limit pricing or entry-preventing pricing. Prices are set above the costs but below prices at which potential competitors could enter the market and earn positive profits. Pricing depends on many factors such as the degree of concentration, economies of scale, product differentiation, the absolute cost advantages of incumbents, and internal interdependence of oligopolistic firms.

Like other post-Keynesians, Nicholas Kaldor (1985) suggests that prices and markups are cost-determined, but he also takes the importance of customer relationships into account. In his view, a firm determines markup based on two opposing considerations: market-share expansion and capital expansion. On the one hand, each firm will choose a price and a markup as low as possible so that they can build up more customers to improve their market share. On the other hand, they also have an incentive to set their markup as high as possible to increase their own capital by means of internal finance. This is because firms want to prevent a situation in which they become financially constrained through excessive reliance on external finance. Note that the second point was usually neglected in the traditional neoclassical theories, in which internal and external finances are considered as near-perfect substitutes. Kaldor therefore views a markup merely as a residual between the cost and the price chosen after considering the market dynamics.

Edmund S. Phelps and Sidney Winter (1970) have provided the first rigorous theoretical analysis of this type of dynamic markup pricing theory. They point to customer-flow dynamics as a barrier to optimal markup pricing.
Marriage

\[ \frac{dn}{dt} = -\alpha(p - p) \]

Here \( n \) is the number of a firm's own customers, \( p \) its own price, \( p \) the average price of all other firms in the industry, and \( \alpha \) a positive constant. Therefore, if a firm charges a high price, it loses customers. They find that equality between marginal cost and price does not generally hold even in a stationary state. Thus an optimal markup is derived as the difference between those two.

**IMPERFECT COMPETITION AND OLIGOPOLISTIC PRICING**

More recent developments in oligopolistic pricing theory focus on *imperfect information* such as "judging quality by price" (Stiglitz 1984), "reputations" (Greenwald, Stiglitz, and Weiss 1984), and "search costs" (Stiglitz 1983) as the source of price rigidities and the markup.

**MARRIAGE**

Transformations in marriage during the twentieth century have inspired a large body of research. Marriage is both a social and legal institution. Although the criteria for who can be legally married vary cross-culturally, marriage is a conjugal state that generally has been reserved for two individuals of opposite sexes, of consenting age, and of no blood relation. Historically, the reasons for, function of, and frequency of marriage has varied by race or ethnicity, class, gender, and the social and economic structures of society. Regardless of such differences, the institution of marriage is viewed by social scientists as one of the most fundamental elements in the maintenance and reproduction of society itself.

Marriage differs in its relation to church and state, though both infer rights and obligations to members of the marital union. Religions often view marriage as a
sacrament that reaffirms religious commitment, whereas wedlock is the legal state of matrimony. Even if a marriage is recognized by the state, it may not be recognized as valid by the church. In practice, church weddings often provide both a legal and religious contract between marriage partners.

Although marriage is defined most often as a union between two opposite-sex individuals, some societies and religious traditions allow for marriage between multiple partners: polygamy. Two forms of polygamy exist. Polygynous unions, in which a man is married to more than one wife, are the most common. Polygyny is currently practiced in some West African countries, particularly among more traditional members of society. When less formal arrangements are included in the definition—such as a man simultaneously being legally married to one woman while engaged in formal consort relationships with other women that are also expected to produce children—the prevalence of polygyny increases substantially. This latter type of polygyny, for instance, is found among wealthier Chinese in China, Taiwan, and the Chinese diaspora in Southeast Asia and North America. Polyandrous marriages, in which a woman is married to more than one husband, are relatively uncommon. Polyandry in the form of marriages to fraternal cohusbands has been reported in some areas of India.

Over time, there has been a shifting focus toward the emotional aspect of marriage in European and North American countries. In the United States prior to the twentieth century, marriage was viewed as a legal contract by which individuals joined in a marital union for social and economic reasons. During this time, marriages were more likely to be arranged by persons not party to the union itself. Following World War I, Americans began to place a greater emphasis on the emotional nature of marriage, and the notion of romantic love in marriage became more important. Furthermore, married persons were expected to invest their emotional energy into the spiritual growth of their marriage partners. The concept of marrying for love varies by cultures today. More industrialized societies are more likely to view love as the primary reason for forming a marital union, whereas less industrialized societies sometimes practice arranged marriage.

Marriage has long been associated with various benefits, including increased health and longevity. Married men in particular are less likely to engage in risky behaviors such as alcohol and drug use. Emotional satisfaction and increased economic well-being are also associated with marriage. Married people are less likely to experience anxiety and depression. Some theorists argue that there is something unique about the institution of marriage that bestows these benefits on the married couple. For instance, a spouse may serve as a monitor of their partner’s health. This is supported by findings that married men are more likely than unmarried men to visit the doctor on a regular basis. Other theorists, however, argue that the benefits of marriage are more a factor of selection bias—that is, people with higher socioeconomic status and better health and emotional well-being are more likely to marry, whereas those lacking these characteristics are more likely to have short-lived marriages that end in divorce, or to forgo marriage altogether.

DEMOGRAPHIC TRENDS IN MARRIAGE

Over time, demographic trends in legal union formation have included changes in legal age restrictions, an overall retreat from marriage in western societies, and women’s increased investment in their own human capital.

Legal age restrictions on who is eligible to marry have varied over time, cultures, and ethnicities. Historically, marriageable age has been closely tied to puberty, and it remains so in many less industrialized countries today. Currently, most North American and European countries have a minimum age of marital consent, usually age eighteen. The U.S. state or jurisdiction allowing for the youngest age at marriage without parental consent is Mississippi at age fifteen for women and age seventeen for men, whereas Puerto Rico requires both genders to be at least twenty-one. However, most states do allow for parental consent, and other statutory requirements may override these minimum age requirements for marriage. For instance, in Massachusetts if parents consent, women can marry as young as age twelve and men as young as age fourteen, whereas other states such as West Virginia, Kentucky, and Louisiana maintain the relatively advanced age of eighteen even with parental consent.

The marriage rate has been in decline in the United States and Europe since the end of World War II. Although the vast majority of people still report a desire to be married (80% of women and 78% of men), and most will eventually do so, there is a continuing trend to delay this step in the adult life course. The median age of first marriage in 1970 was twenty-three for men and twenty-one for women; by 2003 the median age of first marriage had risen to twenty-seven for men and twenty-five for women. (As these figures imply, the age difference between husbands and wives in most developed nations—including the United States—is small.)

A primary factor thought to at least partially account for the decreasing prevalence of marriage in the United States is the increase in women’s human capital. Specifically, women have increased their investment in education, participation in the labor force, and relative annual earnings compared to men. Currently, more women (and men) go to college, thus delaying their eco-
nomic stability and, subsequently, their transition to marriage. In 1970, 13 percent of American women aged twenty-five to twenty-nine had a bachelor's degree or higher, compared to 30 percent of women aged twenty-five to thirty-four in 2000.

The decline in marriage in more industrialized countries has accompanied an increase in female labor force participation. For instance, American women aged twenty-five to thirty-four increased their participation in the labor force from approximately 41 percent in 1970 to 70 percent in 2004. Marriage benefits also vary by gender. Despite their hours worked outside the home, women typically perform the majority of household chores—about 70 percent in the United States. Additionally, married men benefit in the job market more than married women do. Men (especially fathers) often have been afforded a “family wage”—that is, more money to support their families—because of their traditional role as family breadwinners. Women, too, have to deal with social norms, which often view the roles of wife and mother as incompatible with the role of worker. In many Western societies, women's increased participation in nonfamilial roles and investments in their own human capital has begun to close the gap in men's and women's contributions to family income. For instance, in 1987 only 24 percent of all married women earned more than their husbands, but by 2003 32 percent did.

THEORIES OF MARRIAGE

Different explanations exist as to how we select mates to form a unique marital bond. Social-exchange theories focus on the contextual characteristics of the larger marriage market, where individuals compare the assets and liabilities of prospective spouses. Mate selection criteria include income, wealth, home- versus labor-market production, and physical attractiveness. Once the benefits of marriage outweigh the benefits of remaining single for both partners, a legal union is formed. The specialization and trading model adopts a rational-choice perspective that views men and women as attempting to maximize personal gains through marriage. This model asserts that individuals exchange personal assets—be it income, wealth, home production, child-rearing skills, or physical attractiveness—for a partner with the highest overall value on a related set of assets. Historically, men have specialized in and traded on their economic production, whereas women have specialized in and traded on their domestic production.

Career-entry theory is derived from job-search theory, which asserts that potential workers look for employment in the labor market until they find a job that satisfies the minimum qualifications necessary for acceptable employment. From the perspective of the worker, the sorting of individuals into jobs is maximized when the number of jobs available in the market increases. An analogous situation occurs during the process of spousal selection. A person wishing to form a marital union searches for a spouse in the marriage market. As with employment, individuals usually have a predetermined idea of the minimal characteristics necessary before a potential spouse is deemed acceptable. Once in the marriage market, individuals compete with others to find a spouse. High levels of human capital in women decrease the probability of marriage by extending women's marital search process and simultaneously raising their reservation wage for potential husbands. More importantly, from a career-entry perspective, men's economic volatility lowers the probability of marriage by creating long-term financial uncertainty for both men and the women who choose to marry them.

Psychodynamic theories often focus on how childhood experiences and family background influence partner selection. Individuals may model their potential spouses after their opposite-sex parents, or they may create images of the ideal spouse based on childhood experiences. Filter theory posits that we sift through potential mates based on predetermined criteria—often ascribed characteristics such as race and class. Homogamy filters include finding a potential mate that matches your characteristics such as propinquity, physical attractiveness, race, education, income, and religion. Propinquity is typically the strongest homogamy filter. Heterogamy filters include selecting a mate based on characteristics that are opposite such as gender.

Other researchers point to the historical roots of marriage in the system of patriarchy, which views wives as the property of their husbands. For instance, the tradition of wedding rings historically served to solidify a woman’s status as the property of her husband. Until recently, legal views of rape and sexual assault within marriage supported the notion that wives were the property of their husbands. In 1736 the English chief justice Sir Matthew Hale stated that “the husband cannot be guilty of a rape committed by himself upon his lawful wife, for by their mutual matrimonial consent and contract the wife hath given up herself in this kind unto her husband, which she cannot retract” (cited in Russell 1990, p. 17). This statement, which came to be known as the “Hale Doctrine,” was accepted by the U.S. legal system in 1857 under the Commonwealth v. Fogarty decision. Marital rape is now illegal in the United States and in all countries represented at the United Nations's women's conference of 1995. In the United States, however, current laws continue to treat marital rape as a crime less severe, with more lenient sentencing, than other forms of rape.

Nonwestern traditions also support the notion of women as property. The practice of paying a dowry is one
example of how women have been seen as property to be transferred from their parents to their husbands. Under the dowry system, women are an economic liability. To increase a woman’s attractiveness to a male suitor, the family of the bride produces various gifts of economic value to the potential groom and his family. Although this practice is becoming less common under the global capitalist system, various cultures around the world still adhere to the dowry system.

Anthropologists such as Levi-Strauss also note that marriage has been used as a structural tool to form political or commercial alliances across groups. Referred to as alliance theory, it maintains that the universal incest taboo motivates exogamy in marriage through a series of intimate kinship group exchanges of women as the wives of men who are members of a different group. Through this type of generalized exchange a marriage alliance between the two groups is formed and reciprocity is expected. Alliance theory argues that groups’ circulation of women through the practice of trading wives links various social groups together to form complex structures of kinship, and ultimately, society itself.

MARRIAGE ALTERNATIVES

The drop in the marriage rate and the trend in delaying marriage have been accompanied by an increase in alternatives to traditional marriage. Marital dissolution (divorce), cohabitation, nonmarital childbearing, and gay marriage have become increasingly evident in European and North American countries. Marital dissolution in the United States, for instance, increased steadily during the decades following World War II, and began to level off during the 1990s with one in two U.S. marriages ending in divorce.

Cohabitation also has become an increasingly prevalent form of union formation in more-developed counties. Increasing in cohabitation rates have spawned public debate regarding social policies that support the traditional marital union of a husband and wife, and have implications for the popularity of marriage as a larger social institution. Although modern forms of cohabitation were relatively unheard of before the 1960s, by 2003 4.6 million U.S. households were comprised of unrelated opposite-sex partners who were not married. Cohabitation types vary from short-term arrangements, to precursors to marriage, to replacements for legal union formation that is condoned by both church and state. In Sweden, for example, approximately 85 percent of partnered adults aged twenty-five to thirty-four were cohabiting as opposed to living as married couples. In other countries such as the United States, cohabitation is often a short-term arrangement followed by marriage or dissolution of the union. For instance, approximately 70 percent of cohabiting American women marry their residential partner within five years of cohabitation. At the other extreme, 49 percent of cohabiting women dissolve their residential union during the first five years of cohabitation (this figure includes cohabiting women who both marry and divorce within the first five years of the original cohabitation).

As cohabitation has increased, some countries have begun to treat marital and cohabitating unions as legally equivalent. Legal rights inferred to cohabiting couples may include inheritance rights, alimony upon dissolution, retirement benefits for spouses, and streamlined adoption processes. Some other countries, including the United States, continue to distinguish marriage from cohabitation in social and legal policies. A bridge between cohabitation and marriage is available in some U.S. states: Certain states recognize common-law marriages. Under explicit (but varying) criteria—such as the length of time the couple has co-resided, whether they hold joint accounts, assets, and liabilities, and whether the partners refer to each other as “spouses”—cohabiting couples may be considered similar to legally married couples. However, allowances and the requirements needed to establish a common-law marriage vary from state to state.

Rates of childbearing outside of marriage also have been increasing, due in part to the more liberal acceptance of sex outside of marriage and increases in cohabitation and divorce. For instance, in Sweden most children are now born outside of marriage, mostly to cohabiting couples. In the United States, 5 percent of children were born to unmarried mothers in 1960 and this percentage increased to just fewer than 37 percent in 2005. Among non-Hispanic blacks nonmarital childbearing represents nearly 70 percent of all births. Social acceptance of premarital sex also has increased significantly since the 1960s. Despite these trends, people still report that marriage is the ideal situation in which to raise a child. In a survey of high school seniors in 1997 to 1998, only 8 percent of high school seniors stated that unmarried childbearing is a worthwhile alternative lifestyle.

Although marriage often is religiously and legally restricted to the union of two opposite-sex individuals, alternative expressions of intimate-adult commitment are increasingly common. One aspect of marriage that has been gaining public exposure during the twenty-first century is gay marriage. Although the United States generally restricts marriage to a union between opposite-sex adults, other countries allow for individuals of the same sex to marry. In 2001 the Netherlands became the first country to legalize same-sex marriage. Belgium and the Canadian provinces of Ontario and British Columbia followed suit in 2003. In 2004 Massachusetts became the first and only
state in the United States to grant marriage licenses to two persons of the same sex.

Another legal option available to some same-sex couples is the civil union, which is a marriage-like union available in some European countries and in some U.S. states. One example is Germany’s Registered Life Partnership, which grants to same-sex couples legal rights such as sharing a surname, the ability to enter together into contracts regarding property and finances, the right to refuse to testify against your partner, priority in immigration consideration, and health benefits. In 2000 Vermont was the first state in the United States to allow civil unions. Some states (such as California, Connecticut, Hawaii, Maine, New Jersey, and Vermont) allow for domestic partnerships or joint tax returns for same-sex couples. However, many U.S. states have reaffirmed the historical and religious sacrament of marriage between only a man and a woman. Currently, twenty-seven U.S. states have banned same-sex marriage. Eighteen of these have also banned civil unions.

**MARRIAGE, INTERRACIAL**

Marriage is an important social institution. In every society, family values and social norms are in place to prescribe appropriate behavior regarding mate selection. Mate selection follows the pattern of like marries like—people aspire to marry those of the same age, race and ethnicity, educational attainment, religion, or social class. But then, finding an exact match in every characteristic is difficult. Matching based on certain characteristics may become more important than on some others. In most societies religion and race are often the two most important criteria. Religious and racial group boundaries are most likely the hardest to cross in marriage markets. In the United States, religious boundaries are breaking down and interfaith marriages have become more common over recent generations. Marriages crossing racial boundaries, on the other hand, still lag behind. This is not surprising because American society has a long history of racial inequality in socioeconomic status as a result of racial prejudice and discrimination. Race boundary is the most difficult barrier to cross.

Nevertheless, the racial marriage barrier in the United States appears to be weakening as well, at least for certain groups. Americans have had more contact opportunities with people of different racial groups in recent decades.
than in the past because increasingly, they work and go to school with colleagues from many groups. Because racial gaps in income have narrowed, more members of racial minorities can afford to live in neighborhoods that were previously monopolized by whites. Physical proximity creates opportunities to reduce stereotypes and to establish interracial connections and friendships. In addition, mixed-race individuals born to interracially married couples tend to help narrow social distance across racial groups because of their racially heterogeneous friend networks. The growth of the mixed-race population further blurs racial boundaries.

Attitudes toward interracial marriage have shifted over time as a result. In 1958, a national survey asked Americans for the first time for their opinions of interracial marriage. Only 4 percent of whites approved of intermarriage with blacks. Almost 40 years later, in 1997, 67 percent of whites approved of such intermarriages. Blacks were not asked this question until 1972; they have been much likelier to approve of intermarriage, reaching 83 percent in 1997. Social scientists take such expressions of attitudes with a grain of salt. Respondents who answer attitude questions in a survey may simply reflect their desire to fit in with the rest of society. Despite misgivings, people today may feel that it is inappropriate to express reservations about racial intermarriage. Many Americans, it appears, remain uneasy about interracial intimacy generally—and most disapprove of interracial relationships in their own families. Indeed, support for interracial marriage by white Americans lags far behind their support of interracial schools (96 percent), housing (86 percent), and jobs (97 percent). Still, such relationships are on the increase. Nationwide, interracial marriages have increased from only 310,000, accounting for .7 percent of all marriages in 1970, to about 1.5 million, 2.6 percent of all marriages in 2000. The actual number would be much greater if marriages between Hispanics and non-Hispanics were taken into account as well. The upward trend in intermarriage seemingly signals improved racial/ethnic relations, the incorporation of racial/ethnic minorities into American society, and the breakdown of racial/ethnic distinctions. Intermarriage, however, varies widely across racial groups.

RACIAL DIFFERENCES IN INTERRACIAL MARRIAGE

Who pairs up with whom partly depends on the population size of each racial group in the United States. The larger the group, the more likely group members are to find marriageable partners of their own race. The U.S. Census Bureau classifies race into four major categories: whites, African Americans, Asian Americans, and American Indians. Hispanics can belong to any of the four racial groups but are considered as one separate minority group. Although whites form the largest group—about 70 percent of the population—just 4 percent of married whites aged 20 to 34 in 2000 had nonwhite spouses. The percent of interracial marriages is much higher for U.S.-born racial minorities: 9 percent for African Americans, 39 percent for Hispanics, 56 percent for American Indians, and 59 percent for Asian Americans (who account for less than 4 percent of the total population). To be sure, differences in population size for each group account for part of the variation in interracial marriage. For example, the Asian population is much smaller than the white population, which means that one Asian-white marriage affects the percentage of interracial marriage much more for Asians than for whites. Also because of their numbers, although just 4 percent of whites are involved in interracial marriages, 92 percent of all interracial marriages include a white partner. Clearly, racial minorities have greater opportunities to meet whites in schools, workplaces, and neighborhoods than to meet members of other minority groups.

Given population size differences, comparing rates of intermarriage among groups can be difficult. Statistical models used by social scientists nevertheless can account for group size, identify to the extent to which any group is marrying out more or less than one would expect given their population group size, and then reveal what else affects intermarriage. Results show that the lighter a group’s skin color, the higher the rate of intermarriage with white Americans. Hispanics who label themselves as racially “white” are most likely to marry non-Hispanic
whites. Asian Americans and American Indians are next in their levels of marriage with whites. Hispanics who do not consider themselves racially white have low rates of interracial marriage with whites. African Americans are least likely of all racial minorities to marry whites. Darker skin, in America, is associated with discrimination, lower educational attainment, lower income and residential segregation. Even among African Americans, those of lighter tone tend to do better both in the job market and in the marriage market.

**EDUCATIONAL DIFFERENCES IN INTERRACIAL MARRIAGE**

Highly educated minority members often attend integrated colleges, work in integrated surroundings, and live in neighborhoods that are integrated. Although they develop a strong sense of their group identity in such environments, they also find substantial opportunities for interracial contact, friendship, romance, and marriage. College-educated men and women are more likely to marry interracially than those with less education. The fact that Asian Americans attend college at relatively high rates helps to explain their high level of intermarriage with whites. The major exceptions to the strong effect of educational attainment on interracial marriage are African Americans.

Although middle-class African Americans increasingly live in integrated neighborhoods, African Americans still remain much more segregated than other minorities. College-bound African Americans often choose historically black colleges or colleges with a large and potentially supportive black student body. Their opportunities for contact with whites, therefore, are limited. After leaving school, well-educated African Americans are substantially less likely to live next to whites than are well-educated Hispanics and Asian Americans. One reason is that middle-class black Americans are so numerous that they can form their own middle-class black neighborhoods, while in most areas middle-class Hispanic and Asian American communities are smaller and often fractured by ethnic differences. In addition, racial discrimination against African Americans also plays a role. Studies demonstrate that whites resist having black neighbors much more than they resist having Hispanic or Asian American neighbors.

High levels of residential segregation accompanied by high levels of school segregation, on top of a pronounced history of racial discrimination and inequality, lower African Americans' opportunities for interracial contact and marriage. The geographic distance between blacks and whites is in many ways rooted in the historical separation between the two groups. In contrast, Hispanic and Asian Americans' distances from whites have more to do with their current economic circumstances. As those improve, they come nearer to whites geographically, socially, and matrimonially.

**SEX DIFFERENCES IN INTERRACIAL MARRIAGE**

Black-white couples show a definite pattern: About two-thirds have a black husband and a white wife. Asian American–white couples lean the other way; three-fifths have an Asian American wife. Sex balances are roughly even for intermarried couples that include a white and a Hispanic or an American Indian. Clearly, white men have disproportionately more Asian American wives while white women have more black husbands.

In the mid-twentieth century, Robert Merton (1941) proposed a status exchange theory to explain the high proportion of black men–white women marriages. He suggested that men who have high economic or professional status but who carry the stigma of being black in a racial caste society trade their social position for whiteness by marriage. Meanwhile, some social scientists argue that racialized sexual images also encourage marriages between white women and black men. Throughout Europe and the West, fair skin tone has long been perceived as a desirable feminine characteristic; African Americans share that perception. For example, black interviewers participating in a national survey of African Americans rated black women interviewees with lighter skin as more attractive than those with darker skin. But they did not consider male interviewees with light skin any more attractive than darker-skinned men. Other social scientists argue that the sex imbalance is associated with the legacy of slavery. During the plantation era, the miscegenation was mostly marked by white males' exploitation of slave females. The lingering effect of this legacy discourages African American women from marrying whites despite their low rates of in-marriage due to the low availability of marriageable African American men.

Asian Americans have a different pattern; most marriages with whites have a white husband. Some speculate that Asian American women tend to marry white men because they perceive Asian American men to be rigidly traditional on sex roles and white men as more nurturing and expressive. Asian cultures' emphasis on the male line of descent may pressure Asian American men to carry on the lineage by marrying "one of their own." But what attracts white men to Asian American women? Some scholars suggest that it is the widespread image of Asian women as submissive and hyperfeminine. On TV and in cinema, relationships between whites and Asian Americans, though still rare, almost always involve white men and Asian American women. Yet, this image does not explain a smaller but significant proportion of marriages involving white women and Asian American men. Indeed,
education may be part of the reason, given that Asian American men and women have more years of schooling and highly educated minorities are much more likely to marry whites than their less educated counterparts. Yet perceptions of Asian Americans in American society are important as well. Asian Americans are generally believed to be smart, even though the spouses of some whites are not as educated. The stereotype is consistent with the social construction of Asian Americans as a model minority. This belief may well be another reason for a relatively high level of interracial marriages involving whites and Asian Americans.

MARRIAGE, SAME-SEX
Marriage is a vital social institution. The exclusive commitment of two individuals to each other nurtures love and mutual support; it brings stability to society. For those who choose to marry, and for their children, marriage also provides an abundance of legal, financial, and social benefits. In return it imposes weighty legal, financial, and social obligations (see Goodridge v. Department of Public Health 2003).

A growing number of jurisdictions around the world are according legal recognition to same-sex relationships. The types of recognition vary, some jurisdictions according all of the rights and obligations of marriage and others only according some. Similarly, some states within the United States have been expanding the rights and obligations accorded to same-sex couples, although others have acted to restrict or preclude the extension of rights and obligations to same-sex couples and their families.

BACKGROUND
Several countries have recognized that same-sex couples, like different-sex couples, both need and deserve to have their relationships accorded legal recognition. Some countries, such as Spain, the Netherlands, Belgium, and Canada, permit same-sex couples to marry. Other countries, such as France, Germany, Denmark, Norway, Iceland, Finland, Sweden, and Great Britain, offer many but not all of the rights and obligations of marriage.

Some of the differences among these countries include how they treat adoption (e.g., whether international adoptions are permitted), taxes, pension benefits, citizenship (whether at least one of the individuals entering into the relationship must be a citizen of the country recognizing the status), and the presumption of parenthood (whether a child born into the relationship will be presumed to be the child of both adults).

A separate issue is whether families involving same-sex couples will be recognized on a subnational level. Thus, relationships or incidents of relationships might be recognized in a particular city or region, even if they are not recognized nationally. For example, Buenos Aires recognizes civil unions, even though Argentina has not yet decided to do so, and New South Wales, Australia, has legislation regarding how property should be distributed upon the dissolution of a same-sex relationship, even though that is not true for all of Australia.

THE UNITED STATES
In the United States, the states differ greatly with respect to the ways that they treat same-sex relationships. Some states not only refuse to recognize same-sex relationships but also have passed state constitutional amendments pre-
cluding the legal recognition of same-sex marriage or same-sex unions more generally. These amendments have been open to a variety of interpretations. For example, the Ohio state constitutional amendment has been interpreted to preclude the extension of certain domestic violence protections to nonmarital couples, whether composed of individuals of the same sex or of different sexes.

Other states recognize same-sex unions but stop short of ascribing to those relationships all of the rights and obligations of marriage. For example, Hawaii recognizes reciprocal beneficiaries status, which permits both same-sex and different-sex couples to receive certain limited benefits specified by the legislature. California offers a much more robust array of benefits and responsibilities for domestic partners, although even this status is not the equivalent of marriage. Still other states, such as Vermont, accord to same-sex couples the rights and benefits of marriage, but call the relationship a civil union rather than a marriage. As of mid-2006, only Massachusetts recognized same-sex marriage.

Regardless of how the relationship is designated by the state, same-sex couples are not entitled to the numerous federal benefits that are accorded to different-sex married couples, because the U.S. Congress passed legislation in 1996 (the Defense of Marriage Act) specifying that only a marriage between a man and a woman will count as a marriage for federal purposes. The federal statute affects benefits in a broad range of areas, including social security, veteran’s affairs, immigration, taxes, and bankruptcy, among others.

The Defense of Marriage Act was passed for a variety of reasons. Many of its supporters, whether or not they self-identify as part of the Religious Right, cite religious reasons as their justification—for example, by suggesting that God did not intend for same-sex couples to be able to marry. Other supporters worry that recognition of same-sex marriages would be too costly to the state or would somehow devalue different-sex marriage. Those asserting these arguments do not seem to appreciate that the same arguments have been or could be offered to justify preventing many types of marriages, including interreligious, interracial, or intergenerational marriage.

**BENEFITS ON THE STATE LEVEL**

While the Defense of Marriage Act precludes the extension of a substantial number of federal benefits, there are nonetheless a variety of matters of fundamental importance that are determined by state law. For example, there is no national law regarding adoption by same-sex couples—states determine that. There are at least two issues that should be discussed when adoption is being considered. Some states (e.g., Florida) prohibit those with a same-sex orientation from adopting, even if the state permits unmarried individuals to adopt. An individual who had been raising a child for over ten years as a foster parent might be precluded from cementing that relationship through the vehicle of adoption if the would-be adoptive parent is in a relationship with someone of the same sex.

Other states permit gays and lesbians to adopt as individuals. However, they do not permit both members of a nonmarital couple to establish parental relations with the same child, which can result in great difficulties should the adults’ relationship end because of death or estrangement. Suppose, for example, that a lesbian or gay man has custody of a child and is living with a partner. Further suppose that no other adult has parental rights to that child. In many states, the partner will not be allowed to adopt the child, which means that should something happen to the biological or adoptive parent, the child and the partner might be treated as legal strangers to each other.

Refusing to permit both members of a same-sex couple to establish legal relations with a child can have negative consequences, both materially and emotionally. If the partner is not legally recognized as a parent, then the partner’s employer might not recognize the relationship between the partner and the child, which might mean that insurance or other employment benefits would not be extended to that child. The partner might also have more difficulty functioning as a parent, whether when meeting with teachers, visiting the child in the hospital, or authorizing medical treatment. In addition, if the partner will not be recognized by the state as a parent, that individual may have less incentive to form strong bonds with the child, to the detriment of both the partner and the child.

The difficulties that may arise because of a lack of a formally recognized relationship between the partner and the parent’s child can occur analogously if the partners themselves cannot have their relationship formally recognized. If same-sex partners are not permitted to marry, an employer might not recognize the relationship between the two adults, which would mean that insurance benefits might not be extended to the partner. A partner who might otherwise stay home with a child or elderly parent might not be able to do so because of that lack of insurance coverage. Basically, there are a variety of benefits provided by third parties, such as an employer or the government, that will not be available unless same-sex partners can have their relationships legally recognized.

The benefits of legal recognition are nonfinancial as well. For example, hospital visitation and the ability to have a say in medical decision making may depend upon one’s being able to establish a familial relationship with the patient. Were the states to permit same-sex couples to marry, many of these difficulties would be averted.
Marriage is also important because of the protections that will be provided should the relationship end because of death or dissolution. When married couples divorce or one of the parties dies, the state has a system in place specifying how property will be distributed or, perhaps, whether one member of the couple will be ordered to provide support for the other. When same-sex couples are precluded from marrying, they are unable to avail themselves of this system. Perhaps they will make private agreements or other arrangements that will avoid some of the difficulties that are caused by not having access to this system. However, for those who do not make the necessary arrangements beforehand, there is a definite risk that one of the parties may be treated unfairly.

Marriage also has symbolic importance to the parties themselves, as well as to society at large. By precluding same-sex partners from making a public commitment, the state is removing one of the ways that individuals act to strengthen their relationships, which means that the state is removing one of the supporting pillars of long-lasting relationships. Certainly, individuals can remain in committed relationships without marrying, and individuals who do marry may not remain in a committed relationship, so the claim is not that marriage is a necessary or sufficient condition for the maintenance of a healthy or long-lasting union. Further, it may well be that the couple can marry within their faith tradition. That said, however, the state’s recognition of same-sex unions helps add stability to those relationships. Marriage gives individuals security so that they are more willing to invest in and make sacrifices for their relationships, which helps the individuals themselves, their families, and society as a whole.

The refusal to permit same-sex couples to marry has other negative effects as well. It sends a message to society that certain individuals either cannot commit to marriage or, perhaps, do not deserve the opportunity to marry. It also provides a rationale for the imposition of burdens on a particular group that might otherwise be difficult to justify. For example, limitations on adoption and markedly different criminal sentences for sexual relations between adults and minors have been rationalized by appealing to the mere possibility that different-sex couples might marry.

Jurisdictions vary with respect to whether they will recognize same-sex unions and, if they do, whether they will accord those unions the status or the rights and obligations of marriage. When states refuse to accord legal recognition to same-sex relationships, same-sex couples and their families are disadvantaged, so the growing number of jurisdictions recognizing such unions is a development that might be expected to diminish many of the difficulties that such families face.

**MARS**

Since ancient times, the planet Mars has been seen as both a bright red light in the sky and an inspirer of aggressive behavior. Mars is the next planet out in the solar system from Earth, and its relative brightness in the night sky varies more than any other planet. Every two years and seven weeks, Mars changes its appearance from a dim spark to a bright red star. For this reason, Mars has represented a duality to humanity: It is both an inspiring astronomical object and the symbol of the God of War. It was Mars’s variability and red hue which inspired, in the astronomers Nicolaus Copernicus and Johannes Kepler, an intense curiosity concerning its orbit, thus helping spawn the Scientific Revolution in the sixteenth century.

As the Scientific Revolution blossomed, this fascination with Mars continued and changed. Giovanni Schiaparelli’s sighting of “canali,” or canals, in the Martian landscape in 1877, followed by further reports of this phenomena by Percival Lowell, meant that Mars was the possible abode of extraterrestrial life and intelligence. The Lowellian concept of Mars as a dying planet was formed, and it came to be seen by some as a desert planet where a dead or dying civilization might be found. This spawned a host of fictional accounts of Martians, such as the *War...*
of the Worlds by H. G. Wells and the tales of John Carter of “Barsoom” (Mars) by Edgar Rice Burroughs.

Mars also inspired rocket developers such as Robert H. Goddard, and the planet was finally reached successfully by probes, beginning in 1964 with the American Mariner 4, which found a frozen desert covered with water channels, suggesting a previous Earthlike epoch.

In 1976, in a place on Mars called Cydonia, what appeared to be a massive archaeological complex was discovered. On two separate orbits of the Viking A probe, images showed kilometer-sized objects resembling a pyramid near what looked like a carved humanoid face. NASA dismissed the images as illusions, but two engineers, Vincent DiPietro and Gregory Molenaar, investigated the images digitally. One person intrigued by these images was Richard Hoagland, a science reporter formerly with CBS News who organized a team of scientists and engineers called the Independent Mars Investigation Team, which validated the provocative nature of the images. However, Hoagland was criticized by other scientists for sensationalizing the results of the investigation. This effort was motivated by both the compelling nature of the images and the Lowellian folklore of Mars, but it was also a product of the tense cold war atmosphere of the early 1980s. This tension made researchers sensitive to any suggestion of a dead humanoid civilization, fearing the same fate might befall the inhabitants of Earth.

Another aspect of interest in the Cydonia objects was the very humanoid form suggested by the images, which recalled the fascination with the human form of previous epochs. For this reason, the Cydonia images were not only disturbing for their implications but also reassuring in their validation of the human experience, suggesting it is part of something cosmic. Since the cold war ended, Cydonia has become a favorite target of satellite images, which show that the objects are highly eroded, and thus very difficult to characterize. However, despite their eroded character—and continued efforts to dismiss them as merely geological formations—the objects still provoke mystery.

Mars as a whole continues to be an object of intense scientific investigation, with strong suggestions of primitive microbial biology, past and present, and past Earthlike conditions. Thus Mars may yet provide the answer to the age-old question of whether or not humanity is alone in the cosmos. Mars has also become the stated target of human exploration and settlement. Therefore, it can be said that Mars has provoked more human intellectual activity than any other planet and may be the setting for its greatest advances in the future.

MARSHALL, ALFRED
1842–1924

The economist Alfred Marshall was born on July 26, 1842, in London, the second son of William Marshall, a clerk at the Bank of England, and Rebecca Marshall, née Oliver. He was educated at Merchant Taylors School (1852–1861) and took the mathematical tripos (1861–1865) at Saint John’s College Cambridge as “second wrangler,” that is, second in the first class honours list. This achievement gained him a fellowship at Saint John’s, where his interests shifted to the moral sciences, initially philosophy and mental science. Marshall became a college lecturer (1868) and from the early 1870s began concentrating on economics. In 1877 he married Mary Paley, forcing his resignation from his college positions as college statutes then in force prohibited fellows to marry. From 1877 to 1881 Marshall served as principal and professor of political economy at Bristol University College. In 1883 he became a lecturer in economics at Oxford. In 1884 Marshall succeeded Henry Fawcett (1833–1884) as professor of political economy at Cambridge, a post he retained until 1908.

During his professorship at Cambridge, Marshall published his most significant book: Principles of Economics (1890). He had earlier published The Economics of Industry (1879) with his wife and Pure Theory of Foreign Trade and of Domestic Value (1879). Marshall gave most of his evidence to official government inquiries, on monetary and financial topics, on the poor laws, on national income accounting, and on local government finance during the 1880s and 1890s; and served as a member of the Labour Commission (1891–1894), set up by the government to inquire into labor unrest and recommend solutions thereto accordingly.

Marshall greatly expanded opportunities for the study of economics at Cambridge, an effort that culminated in the establishment of an economics and politics tripos in 1903. The Cambridge School of Economics he created was consolidated by his student A. C. Pigou (1877–1959), who became Marshall’s successor as chair.
Other prominent students included John Neville Keynes (1852–1949) in the 1880s, and John Maynard Keynes (1883–1946) in 1905–06. In addition, Marshall was instrumental in the formation in 1890 of the British Economic Association, which became known as the Royal Economic Society in 1902.

Marshall published two further books, *Industry and Trade* (1919) and *Money, Credit, and Commerce* (1923), before he died on July 13, 1924. He left his books and papers to create the Marshall Library at the Cambridge Faculty of Economics and Politics, which honored him in 1932 by establishing the Marshall Lectures. An undergraduate Marshall Society for discussing social questions was formed in 1927.

Marshall’s writings, especially *Principles of Economics*, made major contributions to economic theory. Marshall’s ideas were often succinctly presented in diagrammatic form, a method he pioneered. Facilitating the understanding of real economic problems was a key element in Marshall’s economics, reflecting his desire “to be read by businessmen” and explaining why the *Principles* remained in use as a text until the early 1950s. As a trained mathematician, Marshall also used algebra and the calculus in his economics, visible in the Mathematical Appendix included with all eight editions of the *Principles*. According to him, this was its proper place, since such reasoning could not add anything significant in formulating economic propositions. His frequent use of diagrams in the *Principles* invariably took place in the footnotes, and not in the text.

A major feature of Marshall’s economics was its *partial equilibrium* method, which enabled him to concentrate on the key variable that explained a particular concept, while holding other less important variables constant. For example, his exposition of demand theory is presented primarily as a function of price, other things being equal, including the purchasing power of money, money income, prices of related commodities (substitutes or complementary goods), the time element in the analysis, and tastes, habits, and fashions. This approach simplified functional relationships considerably. However, the complexity of what was impounded in “the pound of *caeteris paribus*” made the method difficult to use in practice, contrary to Marshall’s intentions. Furthermore, its use gave rise to potential logical conflicts; for example, when prices of all other commodities are held constant together with the purchasing power of money, the price of the commodity whose demand is being analyzed needs to vary.

Marshall’s economic analysis in the *Principles* is organized in terms of supply and demand. After two preliminary sections, the *Principles* discusses demand (dependent on price and utility), supply (founded on his theory of production), and their combination to explain value (commodity prices) and distribution (factor prices and factor incomes). Much of Marshall’s analysis is presented in diagrams featuring the *Marshallian cross* of a falling demand curve (reflecting generalized diminishing marginal utility) and a rising supply curve (reflecting generalized diminishing returns), with price the independent variable and quantity (supplied or demanded) the dependent variable, producing the stability, generally speaking, of the resulting equilibrium. Marshall departed from this simple presentation when circumstances demanded, as he did, for example, in his treatment of constant and increasing returns in terms of horizontal and falling supply curves (Marshall 1920, p. 464). However, since economic agents could also make decisions about quantities—for example, how much additional tea to consume, how much additional capacity to install in a factory, which invariably influenced prices—this technique was quite appropriate for Marshall, and following him, Keynes.

Marshall divided supply-and-demand analysis into specific time periods (market, short, and long) reflecting the degree of responsiveness of supply pertaining to them. During the market period, time is too short for supply to alter; supply is unresponsive to changes in price in the short period except from movements in stocks because the period is too short to increase stock by additional production. New output is confined to long-period situations when supply becomes fully flexible from changes in production induced by price changes. These time periods, although measured in clock time, do not reflect clock time per se. They depend on the technical production possibilities for the commodity being analyzed. Marshall also used time analysis for generalizing rent theory to incorporate quasi rent as the income of old capital investments. Like rent, quasi rent is price-determined, but only in the short run, defined as the time required before capital investments can be replaced.

The responsiveness in supply and demand of a commodity to changes in price was classified by Marshall in terms of their degrees of *elasticity*. Where responsiveness is proportionately equal to the price change, *unitary elasticity* applies. When responsiveness is less than the price change, the function exhibits *inelasticity*; if greater, it is described as *elastic*. Elasticity was an important, novel, and enduring feature of Marshall’s price analysis.

Application of Marshall’s theory of value to welfare economics by means of consumer surplus was another enduring contribution. Marshall defined *consumer surplus* as “the excess of the price which a consumer would be willing to pay rather than go without a certain commodity over that which he actually does pay” (1920, p. 124). Consumer surplus provided a measure of the benefit gained by consumers from their environment when indi-
individual consumer surpluses could be added. Marshall also noted that “a pound's worth of satisfaction” differed between people depending on their wealth and income levels, enhancing the difficulties in measuring consumers’ welfare.

Marshall’s theory of production carefully distinguished between the impact of scale and location on the cost of production. Size would generally elicit lower production costs over time. Marshall’s discussion embodied static and dynamic elements, as well as factors incompatible with perfect competition, such as marketing and advertising expenses (Stigler 1941, pp. 77–83). Moreover, by dwelling on the locational advantages for firms as parts of industrial districts—the geographical concentration of industry—Marshall linked scale advantages to the size and concentration of an industry, as well as to the individual firm.

Marshall developed the theory of the firm as an important entity in economic decision making. This was implicit in his treatment of economies and diseconomies of scale, in his treatment of locational advantages, and in his analysis of monopoly and competition as specific market situations where competition meant monopolistic (imperfect) competition rather than an artificial construct of perfect competition. The pupils of Marshall’s pupils, especially Dennis Robertson (1890–1963), Austin Robinson (1897–1993), and Joan Robinson (1903–1983), explicitly produced theories of the firm in their writings, including an innovative study of imperfect competition.

In Money, Credit, and Commerce, Marshall developed the Cambridge cash balance equation as his version of the quantity theory. This equation expressed the demand for money (the amount of income and wealth a person seeks to keep in the form of money) as follows: $D(M) = kPY + k'PW$, where $k$ is the proportion of nominal income ($PY$) held in the form of money, and $k'k'$ the proportion of nominal wealth held in this way. These $k$’s are the inverse of the respective velocities of circulation. Stating the quantity theory in this manner focused on individual demand for cash balances explicable in terms of transaction, precautionary, and speculative demands. Marshall’s manner of looking at monetary relationships was also more amenable to statistical analysis.

Marshall’s role in the history of economic thought is enormous. His Principles is the only nineteenth-century treatise still in wide use more than a hundred years later, even if, by modern standards, it is an unsatisfactory book (Blaug 1997, pp. 404–405). Marshall is the most important figure in economics from the formative decades of the 1890s to the 1920s, when marginalist economics became the dominant theory (Scerpanti and Zamagni 1990, p. 177). Moreover, his theory accepts a general equilibrium framework but is presented in the more realistic and practical partial equilibrium form (Deane 1978, pp. 112–113). The centenary of Marshall’s Principles in 1990 sparked many international celebrations, not only in England at Cambridge and the Royal Economic Society, but in Italy, Germany, France, North America, and even China. Close to 250 articles on Marshall’s economics are collected in the eight volumes of John Wood’s Alfred Marshall: Critical Assessments (1982, 1996). Marshall’s writings clearly continue to be of use to students of economics.

MARSHALL, THURGOOD

1908–1993

In 1967 Thurgood Marshall, who was born in Baltimore on July 2, 1908, became the first African American appointed to the United States Supreme Court. Marshall’s twenty-four-year tenure as a justice was marked by a strong interest in protecting the rights of criminal defendants (e.g., protection against illegal search and seizure) and opposition to the death penalty (Furman v. Georgia,
Marshall, Thurgood

1972). Marshall’s appointment to the Court was part of a successful career as an advocate for the protection of civil rights. Marshall dedicated his career to enhancing access to every arena of public life, with a particular focus on education, housing, employment, and voting. He believed that promoting equal rights under the law was essential to the proper functioning of democracy. According to Marshall, “equal means getting the same thing, at the same time and in the same place” (Brown v. Board of Education, 1954). Marshall’s dedication created a lasting legacy that encompasses numerous aspects of American jurisprudence. He died in Bethesda, Maryland, on January 24, 1993.

EDUCATION AND LAW PRACTICE

Thurgood (born Thoroughgood) Marshall developed an early interest in education. A cum laude graduate of Lincoln University, he believed that education is the only assured means of promoting both individual and communal success. To Marshall and his contemporaries, education was a necessary means of reshaping the status of American race relations.

After graduating from Lincoln, Marshall enrolled in Howard University Law School, where he met and worked with his mentor, Charles Hamilton Houston. As dean of Howard’s law school Houston inculcated in his students a commitment to equal justice and a desire to challenge both legal and extralegal segregation. Paramount to that commitment was an emphasis on overturning the 1896 Plessy v. Ferguson Supreme Court decision. That decision was significant because it created a legal doctrine known as separate but equal and provided the legal justification for segregation in many areas, including education and public accommodations. Marshall was influenced deeply by Houston’s belief that he and other Howard graduates could force the United States to live up to its promise of equality for all Americans. Marshall graduated from Howard in 1933 and opened up a practice in Baltimore that focused on civil rights cases involving issues such as police brutality, civil disobedience, and housing discrimination. Marshall later assisted the Baltimore branch of the National Association for the Advancement of Colored People (NAACP) in its civil rights efforts.

In 1935 Marshall won his first major desegregation case, Murray v. Pearson. Together with his cocounsel, Charles Hamilton Houston, Marshall represented the African American student Donald Gaines Murray, who had been denied admission to the University of Maryland Law School on the basis of its separate but equal admissions policy. Although Murray was a graduate of Amherst College with an impressive academic record, the state of Maryland defended his exclusion, arguing that black students could attend other schools. Marshall had been denied admission to the University of Maryland Law School for the same reason five years earlier. In ruling against the state of Maryland the court of appeals argued that constitutional compliance could not be left to the will of the state. Marshall helped secure the first state-level victory toward overturning Plessy.

Murray became the first in a long line of successes for Marshall. As legal counsel for the NAACP he launched a comprehensive assault on the legally sanctioned practice of exclusion. In 1940 he won his first Supreme Court case, Chambers v. Florida. Over the course of his career Marshall argued thirty-two cases before the Supreme Court; winning twenty-nine, making him the most successful attorney to argue before the Court. As the U.S. solicitor general, appointed by President Lyndon Johnson, Marshall won fourteen of nineteen cases he argued before the Supreme Court.

Marshall successfully argued the 1944 case Smith v. Allwright. The case was significant because it overturned the “white primaries” that were prominent in the South. Marshall helped reduce the gap between the principle and practice of democracy by opening up the political process to all Americans. He continued to attack the separate but equal doctrine in cases such as Shelley v. Kraemer (1948) that struck down racially restrictive covenants. In two cases in particular, McLaurin v. Oklahoma State Regents (1950) and Sweatt v. Painter (1950), he fought against segregation in public education. Sweatt found that the state of Texas’s creation of a separate law school for black students (now Texas Southern University) with inadequate facilities failed to meet the standard of substantive equality.

Although Marshall was successful in arguing the cases, he faced criticism from some black leaders who feared that his legal victories would jeopardize state funding for historically black colleges and universities. Marshall responded to the criticism by stating that “we are convinced that it is impossible to have equality in a segregated system, no matter how elaborate we build the Jim Crow citadel and no matter whether we label it the ‘Black University of Texas,’ ‘The Negro University of Texas,’ ‘Prairie View Institute,’ or a more fitting title, ‘An Apology to Negroes for Denying them Their Constitutional Rights to Attend the University of Texas’” (Sweatt v. Painter, 1947).

BROWN V. BOARD OF EDUCATION

The 1954 case Brown v. Board of Education of Topeka Kansas was the culmination of Marshall’s attack on the separate but equal doctrine. Unlike the prior cases Brown specifically outlawed racial segregation in American primary and secondary schools. Timing was critical for Marshall’s agenda. Armed with his success in integrating
institutions of higher education, Marshall and his NAACP colleagues sponsored five cases affirming their view that separate educational facilities were inherently inferior. Led by Chief Justice Earl Warren, the Court reached a 9–0 decision affirming that “separate educational facilities are inherently unequal” (Brown v. Board of Education of Topeka, 1954). Although Brown did not result in the immediate desegregation of American public schools (see Brown II [1955], Swann v. Charlotte-Mecklenburg Board of Education [1971], and Milliken v. Bradley [1974]), it created a firm foundation for judicial support of the civil rights movement and its efforts to integrate all areas of public and private life.

Marshall’s commitment to protecting the rights and freedoms of individuals was not restricted to the United States. He investigated allegations of racism in the U.S. armed forces in Japan and South Korea and later assisted in drafting the constitution of Ghana. Thurgood Marshall fundamentally redefined the relationship between citizens and their government by promoting equal rights under the law.

MARTYRDOM

Martyrdom is defined as voluntary death for a cause, often for a religious purpose or as the result of persecution. The terminology of martyrdom varies from region to region. The term martyr comes from the Greek martur, which means “witness,” as does the Arabic shahid (pl. shudadā). Martyrs thus bear witness to their cause by sacrificing their lives as proof of its validity. Eastern cultures tend to use words closer to “sacrifice,” focusing on the valor of the agent; e.g., sati, “immolation” after the eponymous Hindu widow who sacrificed herself on her husband’s pyre.

Although martyrdom is historically conditioned, these voluntary deaths have structural similarities, being rooted in traditions of the warrior-hero and religious sacrifice. The noble deaths of kamikaze pilots, Christian martyrs, Indian widows in sati, the Jews who committed mass suicide at Masada in 72 CE, or Moslems on jihad are all sacrifices that transform and sanctify (or divinize) the martyr. Martyrs put their lives on the line, choosing to sacrifice their lives for a cause rather than submit to an opponent and betray their principles. In dying on their own terms, martyrs die heroically, like archaic warriors in battle, sacrificing their lives for the tribe. To their communities, martyrs are god-like in their honor, nobility, and glory. Like King Oedipus or Christ, martyrs are scapegoats and saviors, dying that others may live. Martyrdom is the ultimate and apocalyptic vindication of the martyr’s cause and proof of his or her righteousness. After death martyrs become saints in Christian tradition, divine in Japanese traditions, and hallowed in all traditions.

Martyrdom joins politics and metaphysics. The martyrs’ moral authority becomes a means of confronting an enemy’s superior political and military power, as it did when Antiochus IV persecuted the Maccabees, when Romans persecuted early Christians, when Japanese pilots faced the Allies in World War II, or presently, when Palestinians confront Israel and the United States. Martyrs are marginal agents—crossing the numinous boundary of death, they seek to harness a spiritual power to their own advantage. Being unnatural, voluntary or self-inflicted death is shocking, awesome in the fear and wonder it inspires. Why did the martyr die? If the martyr chose to die, what is worth dying for? At what point is life so
unbearable that one is better off dead? What gave the martyr the strength to face death so bravely?

The power of martyrdom lies in its potential to change society: It forces an audience to think about ultimate questions (if only momentarily) and make moral judgments. These decisions can redress injustices and eventually change the world. Because the death of the martyr invests a cause with meaning, with numen or “weight,” the cause is no longer ordinary. It has been sanctified with the offering of one life; perhaps it is worth the cost of many more. Martyrs draw public attention to the cause for which they died. Not only do they educate the audience, they strive to make their own views normative, converting (if not convincing) their critics. The propaganda value of martyrdom is so great that shrewd opponents avoid martyrizing their enemies, who are more dangerous dead than alive. In the Middle Ages, the cult of saints and the development of pilgrimage sites was of such political and economic importance that relics were stolen, traded, and even manufactured. Today, pilgrims still visit Karbala, Iraq, famous for its Shiite martyrs, and Rome for its early Christian martyrs. Historically, martyrs have meant economic prosperity, political authority, and social eminence.

The dynamics of martyrdom are unusually histrionic, as if the martyr’s ordeal takes place in a transcendent, metaphysical arena or a universal courtroom of conscience that hears the martyr’s case. As J. Huizinga’s theory of play and his game theory suggest, opponents adopt strategies to win, but events unfold unpredictably and are subject to multiple interpretation. Martyrs feel deprived of what they deserve; they challenge existing authorities and offer their case to God and the world at large for judgment. Entrusted to Higher Powers, martyrs and their cause have moved into the realm of the sacred. But the ordeal is also public, a political spectacle in the here-and-now; at any one time, much is “in play,” fluid, indeterminate, and ambiguous.

The martyr’s power comes from holding the moral high ground of innocence and purity. Guilt and unworthiness must be pinned on the opponent. The spectacle of martyrdom is inherently biased in the martyr’s favor insofar as endurance of suffering and death is taken as prima facie evidence that the martyr is in the right—that God is on the martyr’s side. (Otherwise, how could the martyr face such terrible ordeals?) Even if death is clearly self-inflicted, the enemy is held responsible. He has forced the martyr to choose between life on the enemy’s terms and death on the martyr’s terms; he is the guilty persecutor. All martyrdom redounds ultimately to this choice between self-determination and submission to the will of another. Here, the warrior spirit affirms that death is preferable to subjection, dishonor, suffering, and the betrayal of beliefs; whether in Imperial Japan, Christian antiquity, or contemporary Islamic circles, an honorable death is preferable to a life of degradation and misery.

Martyrs seek vindication and retribution for their innocent suffering, some definitive judgment denied them by existing society. Viewed strategically, martyrdom obliges the audience to avenge the innocent or share the guilt of the wrongdoers. If martyrs can turn public opinion against their opponents, they can undermine their enemies’ power. The assassinations of Gandhi, Martin Luther King, and Stephen Biko not only stunned the world at large, they were of such great political consequence that they broke the resistance of the enemy camp. Shifting public opinion often takes the form of boycotts. During the civil rights era boycotts such as the Montgomery bus boycott in 1955 added momentum to the movement for racial equality. In the 1980s, divestment in South Africa hastened the end of apartheid. Individual protests can take the form of hunger strikes (a kind of slow martyrdom), such as that undertaken by suffragettes in their struggle for the franchise, or that of Gandhi, who undertook over a dozen long fasts against the British, or the seventy-five prisoners protesting their illegal detention in Guantánamo in 2005–2006. Such lesser martyrdoms can tweak the conscience of the world audience.

Although the ordeal or spectacle of martyrdom is biased in the martyr’s favor, part of the audience may reject the martyr’s voluntary death, viewing it as “a waste,” “irrational,” and “tragic,” the “pathetic suicide” of a “brainwashed fanatic” or a “selfish act” that disregards family and community. The dead are called “victims,” as if they had not acted willfully, but instead succumbed to circumstances beyond their control. The deaths of such fanatics do not lend credibility to the cause, but discredit it even further, even as the deaths of prominent leaders (or the moral support of living celebrities) lend credibility to a cause.

The intrinsic worthiness of a cause is critical, but not determinative in distinguishing martyrs from fools or criminals. The worthiness of a cause, the social status and deeds of the martyr, the martyr’s behavior under stress, the strength of the enemy, the resources of both sides, and the sequence of actions are all variables “in play.” While dying for freedom is clearly different from dying for the sake of a lost shoe, a range of causes exists whose importance might change in the public eye were a sufficient number of martyrs to bear witness: global warming, animal rights, or the malefiance of corporations (e.g., Enron). The deaths of martyrs invest a cause with meaning, and this is cumulative. When a cause builds up sufficient “weight,” it earns a public hearing and triggers change. In 1963, the self-immolation of the Buddhist monk Thích Quang Dục
in Vietnam opened a flood of media coverage, facilitated by the letters of protest he left behind. Six other monks followed. The event is credited as the final turning point, the death knell of the Diem regime, which collapsed a few months later.

Martyrs lose their power when they lose their innocence, when the greater public rejects their cause and/or refuses to sanction their actions. Then martyrs become enemies (or persecutors themselves) engaged in open warfare with the rest of humanity. The cause must be worth the cost. Martyrs may gain attention and sympathy for their cause by offering their own lives, but they cross a line when others die. Martyrs have no right to deprive others of free choice, not to mention life itself. Belligerent nations in World War II (1939–1945) offer a clear example. Kamikaze pilots accepted that killing Americans was the price of vindicating the purity and divine purpose of their emperor and nation. Validating the cause, they also accepted the cost. But Americans and the Allies rejected the cause of Japan and called it “war.” In the Middle East, the sides are of unequal power, but each has moral claims. To Israelis and their allies, Palestinian suicide bombers are terrorists who murder innocent bystanders, but Palestinians see themselves as victims of an occupation sanctioned by all Israelis and feel justified in fighting against that occupation. To them, Israeli bystanders are casualties in a war that has already cost the lives of many more innocent Palestinians.

Martyrdom operates within that indeterminate field where opinions change and variables are “in play.” Affirmation and rejection are extremes of a continuum; advancement of the martyr's status depends on numerous contingencies. Sooner or later, the martyr's case gains public attention, but rational understanding of the martyr's grievances may not convert an audience driven by equally compelling drives. The audience's capacity for empathy is unpredictable. While historical conditions such as economic security or social similarity increase chances that the audience will identify with victims and feel compassion, studies of authoritarianism demonstrate that personality structure can diminish or even preclude empathy with others. No act of valor, no leader, no matter how august, can convert those who are deeply prejudiced.

What triggers empathy varies. The calculus of martyrdom favors elites, so that the death of one important leader outweighs the deaths of the innumerable nameless. Assassinated in 1980, only Archbishop Oscar Romero is honored as a martyr in the civil war in El Salvador, even though 30,000 others were exterminated by right-wing death squads between 1979 and 1981. The prestige of martyrs sacrificed lends authority to the cause, but the lack of martyrly “quality” can be addressed by an increase in “quantity” (the number of martyrs, the length and intensity of their suffering). All lives are not equal. Certain markers are more valuable than others. In 2003, a young American was killed by a bulldozer as she tried to prevent the Israeli army's destruction of homes in the Gaza Strip. A play based on her letters, “My Name Is Rachel Corrie,” commemorates her life, as does a memorial Web site; she is the subject of various articles, media spots, etc. Corrie is not the first to die resisting the demolition of houses, but she is the first Westerner. Europeans and Americans can identify with such a young, attractive, and highly literate “peace activist,” while Palestinians remain invisible. The less kinship the audience shares with martyrs, the more onerous the martyrs' suffering.

Examples of martyrdom or noble death are nearly universal. These include:

- **Judaism.** Kiddush Hashem (sanctification of the name) is found in Abraham’s binding of Isaac; Rabbi Akiba, who was killed by the Romans in 135 CE; Hannah and her sons; and the killing of Jews in the Rhineland during the First Crusade. A dispute exists about the terminology used for those dying in the Holocaust. Traditionalists argue that Jews did not choose to die and therefore the term “martyr” is inappropriate. They are instead victims, murdered in war. But Yad Vashem (sponsor of the Holocaust Memorial in Jerusalem and the leader in Shoah research and education) calls itself “The Holocaust Martyrs and Heroes Authority.” What matters to most people is that Jews were killed for no other reason than being Jewish.

- **Islam.** A spiritualized definition of martyrdom goes back to the Middle Ages and the distinction between the lesser jihad, the struggle against unbelievers, and the greater jihad, the struggle against evil. Martyrdom lies in intention; death on the battlefield is no guarantee of salvation. In present usage, any observant Muslim who dies gratuitously is a martyr. But martyrdom also has a militant side that goes back to Muhammad’s grandson, Husayn ibn ‘Ali, who was killed at Karbala in 680 in a battle against supporters of the caliphate for leadership of the community. Husayn’s followers are Shiite and martyrdom is an honored goal; those of the caliphs, are Sunni. Also in this militant tradition are the Assassins (from hashish), a secret society of Nizari Isma’ils (schismatic Muslims) who fought against European Crusaders in the Middle Ages. They called themselves fedayeen, meaning those “willing to sacrifice their lives,” a term that survives in the second intifada (September 28, 2000, to the present).
• **Christianity.** Persecuted by Romans, early Christians, like Jews, saw themselves as “dying for God.” Acts or passions record the martyrs’ ordeals, many of which contain purported court records or eye-witness accounts. Protestants memorialized in Foxe’s *Book of Martyrs* date from the sixteenth century, when Catholocs persecuted Protestants in the Counter-Reformation. In Nagasaki, twenty-six Jesuit missionaries were martyred in 1597, and persecution continued under the Tokugawa shogunate costing several hundred lives. In 1981, members of the Irish Republican Army incarcerated at Maze prison went on a hunger strike in protest of the British government’s refusal to grant them status as political prisoners (instead of ordinary criminals). Bobby Sands and nine others died and are widely commemorated in Ireland. In 1998, statues of ten twentieth-century Christian martyrs were unveiled at Westminster Abbey in London, among them, Martin Luther King Jr.

• **Hinduism.** The Hindu practice of *sati* was most frequent in western India from the tenth to nineteenth centuries. Outlawed by the British in 1829, it has survived sporadically up to the present. A new tradition borrowed from Christianity arose with the growth of nationalism in the nineteenth century and the struggle for an independent state in the twentieth century. While Gandhi is the most famous martyr, about a dozen others are deemed martyrs for the cause of Indian independence. While *sati* have altars and are treated as divine, of modern martyrs only Gandhi is occasionally commemorated at an altar.

• **Sikhism.** The Sikh theology of martyrdom (*jihād*) is first found in the Siri Guru Granth Sahib, scriptures compiled by the fifth master and first martyr, Guru Arjan Dev Ji (d. 1606), who called martyrdom “the game of love.” Sikhs have suffered bitterly from persecutions by both Muslims and Hindus. Martyrdom is strongly associated with political resistance and the desire for political as well as religious autonomy, the Punjab being the possible Sikh homeland.

• **Buddhism.** The idea of dying for Buddha does not exist in Buddhism (which is atheistic); the notion of dying for something in the material world is similarly foreign, and Buddhism lacks a history of persecution. Nevertheless, the seven Buddhist monks who immolated themselves in Vietnam protesting the Diem regime’s policies are deemed martyrs in both the East and the West. As with Hinduism, Sikhism, and Islam in modern times, in Buddhism the struggle for freedom and national identity can occasion martyrdom.

**MARX, KARL**

*1818–1883*

By identifying the rational core in the German philosopher Georg Hegel’s writings, the German political philosopher Karl Marx not only clarified the essence of the human mind, but also conceptualized the relationship between Hegel’s subjective and objective mind. Marx suggested that the objective mind had primacy over subjectivity. Identifying the sociohistorical essence of the mind (consciousness), Marx realized that the individual mind was a societal product and that the mind of a single individual was not just the mind of a single person, but that the individual mind was always and necessarily embedded in society and part of society. Marx and his colleague Friedrich Engels discussed the sociohistorical dimension of the mind extensively in their work *The German Ideology* (1932), in which they also suggested that language development paralleled the development of the mind, and that language developed historically from the need to interact with other humans.

Marx’s sociohistorical conceptualization of the mind was part of his view on human nature, which states that the essence of human nature is its societal quality and thus humans should be understood in the context of the ensemble of societal relations. The idea that the mind is in its essence sociohistorical was not in contradiction to the notion of the era that the mind has a natural biological dimension. Marx in fact understood the English naturalist Charles Darwin’s book on natural selection as the natural-historical foundation for his view. The difference between Marx, who regarded Darwin’s theory highly, and Darwin was that for Marx it would be impossible to trans-
fer rules that govern animal behavior to the history of human societies.

According to Marx, because of the sociohistorical quality of the mind, it is exposed to power in contexts and relations of production. This means that the ideas of the ruling class are also the ruling ideas and the ruling ideas are the cognitive expression of the ruling material relations. Thus, morality, religion, and metaphysics cannot be independent. Marx used the metaphor of a camera obscura to describe ideology or false consciousness. Marx knew about psychological phenomena such as optical illusions, the invertive function of the eye, and technological applications such as the camera obscura. He came to the conclusion that the mind has distorted views of the world (optical illusions) and that the mind works upside down (camera obscura). In ideological theories humans and their relations appear upside down but in reality these theories arise from the historical life processes of humans. This metaphor also appeared in Marx's first volume of the Capital (1867) on the fetish character of the commodity. Relationships among human beings appear as relationships among produced things (commodities), and these commodities seem to possess supernatural powers.

Marx connected the mind with power and with labor, the material activities and practices of humans. An analysis of the psychology and philosophy of his time, when cognitive processes were disconnected from real-life activities, demonstrates its significance. Ideas and conceptions of the mind are interwoven with the material activity of human beings. Thus, Marx believed that imagination, thinking, the mental interaction of humans should be understood as the direct outcome of material behavior. The same applies to mental productions as represented in the language of politics, laws, morality, religion, and metaphysics. For Marx real active human beings are the producers of their ideas and they are determined by a particular developmental stage of the productive forces. This conceptualization of the mind led to the famous idea that life is not determined by the mind, but the mind by life. It is not the mind of humans that determines their being, but to the contrary it is the societal being of humans that determines their mind. Although Marx had no doubts about the sociohistorical quality of the mind, he also believed that the mind could be developed further than the zeitgeist, or the existing societal realities of a particular time.

Marx moved according to his philosophy with its emphasis on productive activity (labor), from an objective mind understood by Hegel as law, morality, and ethics, to viewing the objective mind as industry. Accordingly, one should be able to understand the nature of humans in the objectified products of human labor. For Marx the history of industry and the developing objective existence of industry was the open book of human psychology. In the course of this argument, Marx expressed one of the first criticisms of the content of modern psychology: "A psychology, for which this book, the sensuously most tangible and accessible part of history, is closed, cannot become a real science with a genuine content" (1968, p. 543).

In terms of methodology, Marx urged philosophers to study concrete individuals who live in concrete historical societies and not to reflect upon the abstract individual beyond history and society. He suggested a methodology that begins with active humans in order to understand their ideas and imaginations. Human existence and history starts with the fact that humans must be able to live, which includes eating, drinking, clothing, shelter, and procreation. History in its course also leads to the development of new needs and at a certain point in history humans did not only find their means of living but they produced them. Thus, the history of humankind and the history of the mind should be studied in relation to the history of production.

Contemporary psychologists assume more or less implicitly that functions or domains such as consciousness, reasoning, language, memory, or perception belong to an individual mind, and often base their theories and research practices on an individualistic concept of the mind. However, a few psychologists based their theories on Marx's sociohistorical conceptualization of the mind. His ideas inspired the Soviet philosophical psychologist Sergei Rubinstein (1889–1960), the cultural-historical school with its most influential thinker Lev Vygotsky (1896–1934), the French psychologist Georges Politzer (1903–1942), the German thinker Klaus Holzkamp (1927–1995), and various forms of critical psychology. It also can be demonstrated that Marx inspired early American social psychology. In addition, followers of the Frankfurt school merged his theories, yet not his psychological writings, with psychoanalysis, and developed a Freudian-Marxist field of research.

MARX, KARL: IMPACT ON ANTHROPOLOGY
Karl Marx was born in the Rhineland in 1818. He studied law and philosophy in Bonn and Berlin, completing a doctorate at the University of Jena in 1841. His thesis, “The Difference between the Democritean and Epicurean Philosophy of Nature,” explored the earliest materialist philosophies of the two Greek atomists, and demonstrates the inception of a nascent scholarly interest in crafting a sophisticated materialist critique of German idealism. Not surprisingly, his earliest writings, The Economic and Philosophical Manuscripts (1844), as well as the unpublished “Theses on Feuerbach” (1845) and The German Ideology (1845), all represent attempts to conceptualize a practice-oriented methodology for analyzing history and society. This “historical materialist” approach evidences the first engagements between Marx and the work of nineteenth-century anthropology, particularly the writings of Lewis Henry Morgan (1818–1881), Sir Henry Maine (1822–1888), and Johann Jakob Bachofen (1815–1887). Within archaeology, Marx and his frequent coauthor Friedrich Engels (1820–1895) had a profound impact on the cultural historical approach of V. Gordon Childe (1892–1957) in the early twentieth century. And Marx continues to have an important influence on a range of archaeological approaches today, including new structuralist approaches to class analysis (e.g., Saitta 1994). But within sociocultural anthropology, overt reference to Marx did not reemerge until the 1960s. Although much of the reluctance to engage Marx through the first part of the twentieth century can be attributed to a disciplinary reaction against evolutionary theoretical models (especially in U.S. and Canadian anthropology), by the 1940s and 1950s the omission was clearly the product of outright political and scholarly censorship during the “red scares” and McCarthyism of that period. This had the effect of suppressing and ideologically orienting the contributions of U.S. anthropology, which were becoming increasingly dominant globally. As David Price (2004) has shown convincingly, the FBI's intrusions into anthropology during this period were extensive, frustrating and dismantling careers of anyone with activist interests, particularly anthropologists concerned with racial equity and desegregation. Anthropologists with obvious Marxist influence (e.g., Julian Steward and his students, Leslie White, and many others) were not able to claim that influence until the civil rights movement of the 1960s, when broad populist concern with social justice and widespread public disapproval over U.S. actions in Southeast Asia ushered in a new era of social activism.

When Marx did reemerge as a prominent influence in anthropology in the 1960s, he did so in three social theoretical manifestations: through a discussion of the relationship or “articulation” between capitalist and pre-capitalist social forms (particularly within the French Marxist tradition); through an investigation of the mechanics and practice of politics and ideological and class formation; and finally through an interrogation of capitalist influence on non-Western settings (laudably within the cultural ecological and political economic traditions, especially in the United States).

PRECAPITALIST SOCIAL FORMATIONS
A common rejection of Marx stems from the critique that his historical approach was evolutionary and ethnocentrically focused on the socioeconomic experiences of Europe. As a result, many believe his method to be inapplicable to contemporary non-Western societies. Indeed, this explains why in the early twentieth century Marx had a more relevant impact on archaeology than on sociocultural anthropology, which had become frustrated with the unilinear evolutionary claims of nineteenth-century anthropology. In answering this charge, the French Marxist tradition has been particularly interested in the relationship between global and local socioeconomic systems, questioning the relevance of Marx to the study of non-Western societies, particularly in Marx's later works such as the first French editions of Capital, volume 1 ([1867] 1990a) and Grundrisse ([1857] 1978), as well as a long list of unpublished papers and notes. The 1964 publication of Pre-Capitalist Economic Formations, with historian Eric Hobsbawm’s insightful introduction, provided Marx's notes from 1857 to 1858, framing his conceptualization of the development of economic forms in human history. French Marxist anthropologists drew upon Marx's
observations and their own studies of non-Western (principally African and Papuan) societies to query the analysis of societies without centralized political systems. In discussing such societies, where political relationships were based more on kinship or other traditional nonstate forms, they sought to develop a theory of materialism and structural analysis of modes of production that adequately explained transitions between various historical stages (instead of the transitions from feudalism to capitalism and capitalism to socialism and communism that Marx had primarily focused on). French Marxist anthropology is commonly seen as having followed two paths: one influenced by the philosopher Louis Althusser (1918–1990) and his reinterpretation of Capital, which attempted to apply Marxian analysis to all societies in an “overdetermined” fashion; and the other associated with Maurice Godelier (b. 1934), himself a student of the French structuralist Claude Lévi-Strauss (b. 1908), who advocated a more tempered incorporation of Marx’s work that in fact rejected many of Marx’s arguments about noncapitalist societies and economic determinism.

THE ANTHROPOLOGY OF POLITICS: CULTURE, IDEOLOGY, AND A THEORY OF PRAXIS

Marx’s struggle to make sense of the mechanics of class and state formation through dialectics has been influential in the anthropology of politics. Marx’s writing on the state were mostly confined to a series of case studies of France, including The Eighteenth Brumaire of Louis Bonaparte ([1852] 1964c) and Class Struggles in France ([1850] 1964b). Unlike his widely read but hastily composed populist pamphlet The Communist Manifesto, penned with Engels during the height of the European revolutionary events of 1848 (see Marx 1998), these political analyses were written retrospectively because he was forced from France, where he had been an active organizer and journalist, into exile in England. His other notable political analysis, The Civil War in France ([1871] 1933a), a rumination on the Paris Commune of 1871, was produced late in his life, along with his Critique of the Gotha Programme ([1875] 1933b), Marx’s sole, if very vague, attempt to discuss the organization of communist society. Marx’s “Theses on Feuerbach,” in particular his famous eleventh thesis, “the philosophers have only explained the world, the point is to change it,” is widely referenced for its emphasis on the importance of revolutionary practice. Beginning with the civil rights and other social movements in the 1960s, an increasing number of anthropologists became interested in social activism, prompting a thorough investigation of revolutionary politics and interrogation of the work of Marx and his intellectual progeny.

Marx’s writings on politics and the state became influential in the early twentieth century among contemporaries concerned with developing strategies for revolutionary change, notably Antonio Gramsci (1891–1937) and Georg Lukács (1885–1971). Along with some members of the Frankfurt school, including Walter Benjamin (1892–1940), these scholars attempted to make sense of the role ideology and culture played in constraining or driving revolutionary change. Though decisively divergent from Marx’s sociological emphasis on materialist philosophy and historical investigation of the category of labor, they do reflect Marx’s lifelong preoccupation and frustration with the mechanics of socialist transition. The emphasis on culture and ideology has found currency, especially since the 1960s, with many anthropologists uncomfortable with the materialism of Marxian political economy, and often in reaction to the heavy-handed technological or environmental determinism of cultural materialists such as Marvin Harris, Michael Taussig and Jean and John Comaroff, with their concerns with investigating the symbolic organization of capitalist relations embedded in the politics of the state, fetishization, and cultural and religious institutions, are well-known for this kind of Marxian political tradition.

ANTHROPOLOGY, POLITICAL ECONOMY, AND GLOBALIZATION

Beginning in the 1940s and 1950s a group of scholars based in New York (including Elman Service, Stanley Diamond, and Julian Steward and his students, such as Eric Wolf and Sidney Mintz) spearheaded a new theoretical and methodological movement against a U.S. anthropology that for several decades had emphasized a more isolated approach to the study of individual cultures. Beginning with emphases on environment, ecology, and materiality, their approaches gradually evolved toward a sophisticated political economic analysis intent on assessing the impact of capitalism in non-Western societies, particularly in areas with a long history of entrenchment global processes, such as Latin America and the Caribbean. At the same time, anthropologists were influenced by numerous interdisciplinary studies of capitalism and development, including those by Andre Gunder Frank, Immanuel Wallerstein, Samir Amin, Walter Rodney, David Harvey, and others. There is a long list of anthropologists interested in the effects of capitalism on their subjects of study, some of whom have a more direct connection to materialist and cultural ecological approach than others. But regardless of their intellectual kinship, studies of political economy in anthropology from the early 1980s to the present can be divided, more or less, into two groups: one set of studies analyzing primarily the agency of subjects reacting to capitalist labor processes;
and the other focused on material objects (commodities) as entry points for understanding socioeconomic organization.

The first, subject-centered, track includes the many discussions of discipline, power, and alienation developed through the capitalist labor process, and typically they rely on Marx's more subject-oriented discussions of capitalism, such as his four-tiered typology of alienation in Economic and Philosophical Manuscripts ([1844] 1959). Since the 1980s anthropologists have produced a number of ethnographies analyzing capitalist power and discipline in global contexts, especially in the areas of industrial production and the exploitation of women and peasants, as well as rich analyses of flexibility in response to changing capitalist strategies of production. Aihwa Ong’s 1987 discussion of Malaysian women factory workers and June Nash’s 1979 study of Bolivian tin miners stand out as exceptional ethnographies that describe the structuring of and responses to labor transformation and alienation.

Thesecond, object-oriented, variant of this political economic tradition relies more methodically on Marx's analysis of the commodity in Capital (1990a; 1990b). Sidney Mintz’s groundbreaking study of the history of sugar production in Caribbean slave economies and its influence on the development of capitalism in Europe provides a model for this kind of political economic study (Mintz 1985). Focused on particular commodity objects and the global ordering of social relations that follows their cycles of production, exchange, distribution, and consumption, this “commodity biography” approach has proliferated not only in anthropology, but indeed across the social sciences (for summary, see Mantz and Smith 2006, pp. 78–80).

MARXIAN FUTURES?
Since the 1980s fewer anthropologists have been willing to claim identification with Marxism. The reasons are threefold. First, a disciplinary preoccupation with anthropology's colonial legacy has resulted in a reluctance to assert generalizable or lawlike claims about the cultural concept. Marxist approaches, as with other purportedly “grand narrative” approaches, have been decried in some circles as overly functionalist and even ethnocentric in their obsession with the global role of capital. Second, there was a general apathy toward the work of Marx following the end of the cold war. It is worth noting that the recent electoral victories by Marxist politicians throughout Latin America have no doubt contributed to a reenergizing of interest in Marxian scholarship in this area. Lastly, anthropologists appear to have embraced the more comfortable category of globalization as a way of understanding the wider net of capitalist influences around the world. Despite these ominous postscripts, this last point should be taken to demonstrate the indelibility of Marxian influence in spirit, if not in practice, throughout a discipline that can no longer see its subjects as removed from an increasingly relevant and pervasive global capitalist organization.

MARX, KARL: IMPACT ON ECONOMICS
Karl Marx’s economic analysis is mainly contained in
three books: the three-volume Capital, the Theories of
Surplus Value, also in three volumes, and the Grundrisse.
In his economic works Marx tries “to lay bare the law of
motion of modern society,” that is to say, to discover social
regularities described mainly as long-run tendencies.
Marx’s method of analysis begins with the observation of
empirical reality in all its complexity and concreteness.
From this reality he derives abstract concepts (determina-
tive relations and interpretative categories), and then
through these concepts he ends up once again with the
concrete, whose reproduction now is structured according
to the internal connections established by the theory. The
adequacy of the theory and concepts that have been cre-
ated is judged by the degree of correspondence between
the most concrete categories and data derived from empiri-
cal reality. A characteristic example of this methodologi-
cal approach is the determination of market prices (the
most concrete category) by another set of more abstract
prices known as prices of production, that is, prices that
incorporate the economy’s general rate of profit. Prices of
production are in turn determined by an even more
abstract type of prices called labor values. All these prices
can be subjected to empirical testing.

Marx observes that capitalism is a historically specific
system characterized by generalized commodity exchange
and so, naturally, the starting point of his inquiry is the
analysis of the commodity whose exchange value aspect
(and not its use value aspect) is the dominant one.
Exchange value is the external measure of the intrinsic
property of commodities, which he calls value, defined as
the total amount of socially necessary abstract (i.e., undif-
fferentiated) labor time embodied in a commodity. In the
process of exchange, one commodity, due to its possession
of a set of useful properties, is chosen to function as the
universal commodity against which all other commodities
are compared and exchanged. The commodity that histori-
ically has performed the function of universal commodity
more successfully than any other is gold. The ratio of the
value of a commodity to the value of gold gives the direct
price of the commodity. If the value of gold decreases
(e.g., because of discoveries of new gold mines and tech-
nological change) the general price level, other things
being constant, increases—and vice versa. This rudimen-
tary theory of money, which is derived from a straightfor-
ward generalization of the theory of value, can be ex-
anded to include both monetary systems that are con-
vertible to gold and those that are not, and thus becomes
relevant for new developments after 1970. At the same
time, Marx’s theory of value (together with the use of
mathematical analysis and input-output data) has been
shown to rather accurately predict market prices, and thus
could become a viable alternative to neoclassical price the-
ory (Shaikh 1984).

The analysis of the universal commodity and money
leads to an investigation of the capitalist process of pro-
duction. This process is described by the circuit \( M \to C \to L \to P \to C’\), according to which capitalists
invest an amount of money \( M \) in order to buy a set of
commodities \( C \) consisting of commodity labor power
\( L \)—that is, the worker’s capacity to work—and other
means of production \( M_P \), for the purpose of production
\( P \) of a new set of commodities \( C’ \), which when sold
they expect to realize a sum of money greater than that of
the initial investment, \( M’ > M \). This extra money is what
really motivates the whole circuit of capitalist production
as it is repeated on an expanded scale. The difference
\( M’ - M > 0 \), which Marx calls surplus value, stems from
labor power, a special commodity characterized by its
property of producing more value than the value of com-
modities that the worker buys with his money wage and
consumes in order to reproduce his capacity to work. In
contrast, the value of the means of production is either
transferred to the final product all at once (as in the case
of raw materials) or gradually through depreciation (as is
the case with the plant and equipment) (Capital I). The
distinction between labor and labor power is Marx’s great-
est discovery and contribution to political economy,
because through this distinction the source of surplus
value can be explained on the basis of equivalent
exchanges. Marx argued that surplus value is created in the
sphere of production by labor. The production sphere has
primitacy over the circulation sphere because the latter is
supported by the surplus value produced in the former.
Furthermore, the circulation sphere modifies and changes,
within strictly specified limits, some of the results of the
sphere of production. For example, surplus value in the
sphere of circulation is redistributed to the various sectors
of the economy in the form of profit according to its
degree of capital intensity; however, the sum of the prof-
its cannot exceed the amount of surplus value produced.

It is important to stress that there is no guarantee that
the circuit of capital will necessarily be completed, as it
can be interrupted at any stage by a number of unexpected
factors. Thus, uncertainty and expectations are immanent
in Marx’s analysis of capitalism. Furthermore, the whole
circuit begins and ends with money, a characteristic that
allows the introduction of credit and also the hypothesis
that savings may differ from investment, a difference that
sets the stage for the development of an alternative to
Keynes’s theory of effective demand rooted in the process
of capital accumulation.

According to Marx, the hallmark of the individual
behavior of capitalists is the pursuit of profit as a purpose
in itself, which forces them into two kinds of competition: the first with workers in the labor markets over wages and conditions of work, and the second with other capitalists in the commodity markets over the expansion of market share at the expense of their competitors. Capitalists cope with these two types of competition through the introduction of more fixed capital. As a consequence, mechanization of the labor process is used to raise the productivity of labor. The introduction of fixed capital both increases the scale of operation needed for minimum efficiency and reduces the unit cost of production. The latter implies that by reducing their prices innovating firms are able to expand their market share at the expense of less efficient firms. Thus, the process of capital accumulation leads to a small number of top firms controlling an increasing share of the total market. This is the reason why concentration of capital is the expected outcome implied by the nature of capital and by the operation of competition, which by no means diminishes over time. On the contrary, the very cause of mechanization—the pursuit of profit—continues to exist even with fewer firms, as competition among them intensifies. Meanwhile, the ever-increasing minimum-efficiency scale of operation requires higher investment that firms, especially the small ones, cannot undertake on their own, and thus there is pressure to merge, in order to avoid becoming the target of a hostile takeover. The resulting growth in the scale of production through the amalgamation of capitals is called centralization of capital and is another aspect of the operation of competition (Capital I, III). If there is a grand prediction that has been historically validated it is Marx's law of increasing concentration and centralization of capital.

Another grand prediction by Marx, which is also consistent with the available historical evidence, concerns the law of the falling rate of profit. This law is derived from the very purpose of capitalist production, which is the extraction of profits as an end in itself. As mentioned above, the realization of this goal entails mechanization of the production process through the introduction of fixed capital. On the one hand, this raises both the productivity of labor and profits for the firms that remain following concentration; on the other hand, however, the increase of fixed capital relative to labor leads to a falling profit rate. Marx noted that the fall in the rate of profit exerts a negative effect on the mass of real profits and, at the same time, a positive effect through the accumulation of capital. So long as the positive effect exceeds the negative, the mass of real profits expands at an increasing rate in a long wavelike pattern. Because new investment is a function of the rate of profit, it follows that a falling rate of profit at some point will necessarily slow down the rate of growth of new investment, thereby slowing down the rate of increase in the mass of real profits. As this tendency continues there will be a point at which the two (positive and negative) effects will cancel each other out and the change in the mass of profits will become zero. This means that the investment of the previous period will not contribute at all to an increase in profits and thus capitalists will have no interest in new investment. This is the point of “absolute overaccumulation of capital” that marks the onset of economic crisis. Its consequence is a slowdown in investment and rising unemployment. As more and more firms are led into bankruptcies and real wages fall, one can also observe the creation of new institutions, the emergence of new methods of management, and the diffusion of technological change. The combination of these processes results in a rising mass of profit (and a temporarily rising rate of profit) and sets the course for the reestablishment of the necessary conditions for another wave of expansion and contraction. Thus capitalism is both a growth- and crisis-prone system, as has also been documented in the literature on long economic cycles (see Shaikh 1992).

Marx's impact on economic thought has not received the recognition it deserves due to his view of the historical character of capitalist society and his vision of socialism. Thus, unfortunately, when orthodox economists discuss aspects of Marx's work, they generally do so to point out its alleged weaknesses rather than its strengths.

MARX, KARL: IMPACT ON SOCIOLOGY

The ideas of Karl Marx (1818–1883) on alienation, historical change, class relationships, the capitalist system, and social revolution have had a lasting impact on sociology, though interest in his work has fluctuated and sociologists have not always agreed about its relevance. In the classical period, for example, Émile Durkheim's 1897 "Review of Antonio Labriola, 'Essais sur la conception
matérialiste de l’histoire’’ (Essays on the Materialist
Conception of History, 1896) argued that the materialist
conception of history—which he believed Marx’s The
Communist Manifesto (1848) represented—was unproven
and contrary to established facts. In “Bureaucracy,”
(1921) Max Weber offered a critical estimation of a socialist
program’s likelihood of success, while his The
Protestant Ethic and the Spirit of Capitalism (1905)
forwarded an idealist explanation of capitalism’s rise to complement Marxist-materialist accounts.

Georg Simmel’s The Philosophy of Money (1900) and
Ferdinand Tönnies’s Gemeinschaft und Gesellschaft
(Community and Society, 1887) were also, in part, motivated by Marx’s view of modernity as a unique historical experience. While these classical theorists approached Marx from a general sociological vantage point, later scholars adopted a Marxist perspective from which to consider sociological questions, including the influence of class structures on the state, the human sciences, and popular culture, as well as the dynamics of social stratification systems.

In early twentieth-century Europe, Italian Marxist
Antonio Gramsci (Selections from the Prison Notebooks) inquired into how the ruling class’s cultural “hegemony” can shape social institutions and thwart revolutionary spirit and action. In Germany, Georg Lukács similarly examined the relationship between History and Class Consciousness (1923). In his widely read and debated Ideology and Utopia (1929), Karl Mannheim (Hungarian born, schooled in Germany and France) tapped into Marxist ideas for research on the sociology of knowledge. Scholars at the Institute for Social Research—later known collectively as the Frankfurt school and including most notably Herbert Marcuse (Reason and Revolution, 1941; One-Dimensional Man, 1964), Max Horkheimer (Critical Theory, 1968), and Theodor Adorno (Negative Dialectics, 1966)—examined how commodity markets and bureaucratic planning shape science and popular culture (e.g., Horkheimer and Adorno 1972). Also in Germany, Jürgen Habermas adopted similar questions but further asked how ruling classes and their state representatives might suffer a Legitimation Crisis (1973), as well as how free communicative spaces can exist within the rubric of bureaucratic capitalism (The Theory of Communicative Action, vols. 1 and 2, 1981).

In France, Georges Canguilhem (Ideology and Rationality in the History of the Life Sciences, 1977) and Maurice Merleau-Ponty (Adventures of the Dialectic, 1955) appealed to Marx’s ideas in their research on the human sciences. Their wider influence came through their students, most notably the structuralism of Louis Althusser (For Marx, 1965) and the poststructuralism of Michel Foucault (The Archaeology of Knowledge, 1969; Discipline and Punish, 1975). Later postmodern theorists such as Jacques Derrida (Spectres of Marx, 1993) and Ernesto Laclau and Chantal Mouffe (Hegemony and Socialist Strategy, 1985) were sympathetic to Marx’s views for capturing the contemporary moment and animating political struggle, though they argued for incorporating nontraditional Marxist concerns such as racial, gender, national, and sexual identities into radical politics.

In England, historian E. P. Thompson’s The Making
of the English Working Class (1963) provided insight into class dynamics and historical social change, while Ralph Miliband (The State in Capitalist Society, 1969) debated Greek theorist Nicos Poulantzas (1969) on the relationship between social classes and the state—that is, “relative autonomy” versus “instrumentalist” theories. This dialogue inspired reexaminations of political power in Marxist terms, such as those found in Bob Jessop’s The Capitalist State: Marxist Theories and Methods (1982). Also in England, Anthony Giddens adopted features of Marx’s materialist approach in constructing New Rules of Sociological Method (1976) and his theory of “structuration” (Giddens 1984).

Outside the centers of European power, others picked up Marxist questions. African Marxist Frantz Fanon’s The Wretched of the Earth (1961) offered a trenchant critique of French imperialism in Algeria. In Latin America, economist Raúl Prebisch’s The Economic Development of Latin America and Its Problems (1950) examined relations of unequal exchange between “core” capitalist societies and those on their “periphery” in the world market. This perspective influenced dependency theory, whose main advocate was the German American scholar Andre Gunder Frank (Capitalism and Underdevelopment in Latin America, 1967). Frank argued that the “underdeveloped” conditions of many countries in the Americas resulted from economic and political exploitation visited upon them by capitalist powers. This perspective attracted the attention of Chilean president Salvador Allende and former Brazilian president Fernando Henrique Cardoso while in political exile.

In the United States, where Marx was generally eclipsed for the first half of the twentieth century, economist Paul Sweezy’s works, The Theory of Capitalist Development (1942) and Monopoly Capital (1966), were influential in keeping a Marxist dialogue alive. The postwar period found sociologists such as C. Wright Mills using Marx’s (and Weber’s) work for a critical analysis of The Power Elite (1956), which was said to dominate political, economic, and military institutions. Adopting dialectics as his viewpoint, Bertell Ollman (1968) revealed the objective and subjective elements in Marx’s approach to class and examined how the humanism in his early works shed light on the question of alienation (Alienation: Marx’s
Having previously fled Nazi Germany (Adorno and Horkheimer found a home at the New School for Social Research in New York City and Marcuse at the University of California, San Diego), Frankfurt school scholars and American Marxists, in combination with the U.S. political-cultural climate in the 1960s and 1970s, made conditions conducive for a new generation of scholars to rediscover Marx. Interest in Marx’s humanism and alienation brought attention to the Frankfurt school’s work on the culture industries and the mass media in the works of Douglas Kellner and Stuart Ewen. Other theorists of popular culture, such as Frederic Jameson, followed the postmodern lead to inquire about “the cultural logic of late capitalism.”

Marx’s impact on sociology advanced elsewhere on both theoretical and research fronts. Marx’s political economy inspired Althusser’s structural Marxism, which theorized the operation of social structures outside of human agency, and analytical Marxism, which placed the rational actor at the center of analysis (Elster 1985; Roemer 1986). One influential perspective sharing this latter approach was Erik Olin Wright’s (1976) work on the “contradictory class locations” in advanced capitalism, as well as his studies of Class, Crisis, and the State (1978). Theda Skocpol’s States and Social Revolutions (1979) advanced class analysis through a historical-comparative study of state formation, while Michael Burawoy (1990) examined how Marx’s scientific commitments inform the history of political strategies of radical movements. Scholars outside of conventional Marxism, such as feminist theorists and criminologists (Richard Quinney), increasingly incorporated Marxist ideas in an intellectual climate that also brought renewed attention to the work on race relations previously done by W. E. B. Du Bois and Oliver Cox, each of whom Marx had influenced.

Perhaps the most influential strand of Marxist thought has been Immanuel Wallerstein’s (1974–1989) World Systems Analysis. This perspective arose in dialogue with Russian theories about Asiatic modes of production, the French Annales school and its analyses of historical periods of the longue durée (Marc Bloch, Lucien Febvre, Fernand Braudel), and Latin American theorists of unequal exchange and other dependency theorists (world-systems analysis). After their introduction into the discipline, Wallerstein’s models of core-periphery relations, the interstate system, long waves of capitalist development, the rise of antisystemic movements, and the transition out of the capitalist world economy have ever since shaped the work of world-systems analysts. Used in studies of development, social stratification (including race, class, and gender studies), and the sociology of knowledge, world-systems analysis arguably reached the status of a paradigm in itself by the late twentieth century.

Throughout the second half of the twentieth century, the number of journals devoted to Marxist studies proliferated, including the New Left Review (1960), Capital & Class (1977), Thesis Eleven (1980), Praxis International (1981), Critical Sociology (1987; formerly The Insurgent Sociologist, 1969–1987), Rethinking Marxism (1988), and Historical Materialism (1997). Not limited to sociologists, these journals provided a home for a wide variety of Marxist scholarship, something less in evidence in sociology prior to the 1960 to1970 period. Marxist scholars also increasingly found professional institutionalization within reach both in the university system and in sociology’s major organizations. For instance, in 1975 the American Sociological Association officially incorporated a Marxist section.

Marx’s political-economic, materialist, and dialectical thought continues to inform research programs in sociology. Control of productive resources is a source of social power in capitalist society, shaping the conditions of work, discourse in the mass media, and state policies worldwide. These relationships have grown in scope since Marx’s day, as have attempts by antisystemic movements to find local autonomy, cross-national cooperation, and solutions to ecological crises. With capitalist society and how to study it as its central subject matter, Marx’s work remains a source of insight for all sociologists interested in studying the origins, the structure, and the nature of the change within the capitalist system.

**MARXISM**

Marxism is a family of critiques, theories, and political goals loosely organized around the theories and criticisms formulated by Karl Marx (1818–1883) in the middle of the nineteenth century. Central to this body of theory are several key ideas: the view that capitalism embodies a system of class exploitation; that socialism is a social order in which private property and exploitation are abolished; and that socialism can be achieved through revolution. Revolutionary leaders and theorists, and several generations of social scientists and historians, have attempted to develop these central ideas into programs of political action and historical research. The challenges for Marxist political parties fall in two general areas: how to achieve revolutionary political change (the problem of revolution); and what the ultimate socialist society ought to look like (the problem of the creation of socialism).

Marx was an advocate for socialism and for the ascendant political power of the working class (Newman 2005). His analysis of the need for political action by the proletariat was most fully expressed in *The Communist Manifesto*, jointly authored with Friedrich Engels. He was one of the early leaders of the International Workingmen’s Association (the First International), founded in 1864. However, Marx’s economic and political writings provide very little concrete guidance for the design of a socialist society. Socialism was to be an order in which exploitation and domination were abolished; it was to establish an end to the dominion of private property; it was to create an environment of democratic self-determination for the proletariat. Marx’s own definition of socialism might have included these elements: collective ownership of the means of production, a centralized socialist party, political power in the hands of the proletariat, and the view that socialist reform will require the power of a socialist state. Marx also emphasized human freedom and “true democracy”—elements that could have been incorporated into nonauthoritarian forms of democratic socialism.

Much of the political platform of twentieth-century Marxism took shape following the death of Marx through a handful of more authoritarian theories, including especially those of Vladimir Lenin (1870–1924), Joseph Stalin (1878–1953), and Mao Zedong (1893–1976). The most catastrophic ideological results of twentieth-century communism bear only a tangential relationship to Marx’s writings; instead, they bear the imprint of such revolutionary thinkers as Lenin, Stalin, Leon Trotsky (1879–1940), and Mao. Perhaps the most crucial flaw within twentieth-century communist thought was its authoritarianism: the idea that a revolutionary state and its vanguard party can take any means necessary in order to bring about communist outcomes. This assumption of unlimited political authority for party and state led to massive violations of human rights within Soviet and Communist regimes: Stalin’s war on the kulaks (rich farmers), the Moscow show trials, the Gulag, Mao’s Great Leap Forward and its resulting famine, and the Chinese Cultural Revolution. The dramatic economic failures of centralized Soviet-style economies derived from a similar impulse: the view that the state could and should manage the basic institutions and behaviors of a socialist society (Kornai 1992).

It is possible to formulate a nonauthoritarian conception of socialism based on a democratic socialist movement and a theory of a democratic socialist society. Indeed, it is possible to find support for such conceptions within the writings of Marx himself. The most influential Marxist parties of the twentieth century took another avenue, however. These parties emphasized the “dictatorship of the proletariat,” the need for the working class to seize power by force, and the conviction that the “bourgeoisie” and its allies would not tolerate a peaceful transformation of the defining property relations of capitalism. The Bolshevik seizure of political power in the Russian Revolution (1917), the failed Spartacist uprising in Germany in 1918, and the Chinese Communist Revolution in 1949 all embodied the assumption that only a disciplined central party, supported by the masses, would be able to exercise the power necessary to overthrow the capitalist ruling class; and only a disciplined Communist government would be capable of enacting the massive social changes required for the establishment of communist society once in power. The dominant political ideology of communist parties and states in the twentieth century was antidemocratic and ruthless in its use of violence against its own citizens. (One of the few examples of a socialist regime that willingly submitted itself to popular referendum, and accepted defeat, was the government of Daniel Ortega in Nicaragua in 1990.)

Soviet Communism represented the earliest and most pervasive ascendency by a communist party. After the seizure of power in the Russian Revolution, Lenin and Stalin exercised political power to force the rapid transformation of Soviet society and economy, and to preserve the power and privilege of the Communist Party. There was deep disagreement among the party’s leadership about the right course for Soviet Communism. How should the development of agriculture and industry be balanced? How rapidly should socialist transition be performed?
How should the forces of the market and the state be involved in socialist transition? One school of thought advocated a gradual transformation of the Soviet economy and system of production, permitting the workings of market institutions and the emergence of an industrial bourgeoisie that would advance Soviet industrial capacity. The other school was ideologically opposed to permitting a propertied class to acquire power, and advocated a state-directed and more rapid transition to socialism. The New Economic Policy (NEP) of 1921 embodied the former strategy, and it was decisively rejected by 1928. From that point forward, Stalin demonstrated his intention of using the power of the state to force social changes that would propel the Soviet system into its communist future. Stalin’s determination to defeat “counter-revolutionary kulaks” during the period of collectivization of agriculture brought about the deaths by starvation of several million rural people in the Ukraine, as a deliberate act of policy (Viola 2005). The doctrine of “socialism in one country” led the Soviet-dominated Communist International to sacrifice other socialist parties (for example, during the Spanish Civil War) in favor of the interests of the Soviet system. Stalin’s internal political and ideological struggles within the party led him to pursue a murderous campaign against other Communist leaders and ordinary people, resulting in show trials, summary executions, and the consignment of millions of people to remote labor camps. (See Smith 2002 for a good summary of these events.)

China’s Communist Revolution was guided by Mao Zedong from its early mobilization in the 1920s, through civil war and anti-Japanese war in the 1930s and 1940s, to successful seizure of power in 1949 by the Chinese Communist Party (CCP) and the Red Army. Mao’s Marxism was strongly influenced by Soviet ideology, but also incorporated the perspective of the role of the peasantry in revolution. Classical Marxism placed the proletariat at center stage as the revolutionary class, but Mao’s urban proletariat strategy was destroyed in 1927 when the Republican army under Chiang Kai-shek (1887–1975) massacred the Shanghai Communist Party organization. This precipitated the Long March and Mao’s regrouping around an ultimately successful peasant-based strategy for revolution. China’s communist leaders too faced fateful policy choices: whether and how to implement “social ownership” of agriculture and industry, how to achieve rapid industrialization and modernization, how to create the political conditions necessary to sustain Chinese socialism and socialist identity among the Chinese population, and how to confront the capitalist world. China’s history since 1949 has pivoted around these issues: the Great Leap Forward (1957), in which China underwent rapid collectivization of agriculture, and an ensuing famine that resulted in tens of millions of deaths; the Cultural Revolution (1966–1976), in which Red Guards throughout the country persecuted and punished teachers, officials, and others for political purity; the reform of agriculture toward the Family Responsibility system in the 1980s, resulting in a surge of productivity in the farm economy; and the rapid economic growth of the 1990s into the first part of the twenty-first century. Developments since 1980 reveal a more pragmatic and market-oriented approach toward China’s development on the part of CCP leadership. At the same time, the Chinese government’s crackdown on the democracy movement in 1990 at Tiananmen Square demonstrated the party’s determination to maintain control of China’s political system.

Anticapitalist politics of the early twentieth century were influenced by several strands of activism and theory that were independent of Marx’s thought, and these strands found expression in the solutions and platforms of Marxist political parties and movements. Anarchist thinkers, such as Mikhail Bakunin (1814–1876) and Peter Kropotkin (1842–1921), put forward the radical view that all forms of state power were inherently evil. Anarchism and syndicalism had significant influence on radical labor unions in Europe and North America. Revisionist socialists, such as Eduard Bernstein (1850–1932), argued that revolution by force was not a feasible path to socialism and advocated instead for gradual change from within capitalism. Democratic thinkers emphasized the ability of groups of people to govern themselves, and to press their states to undertake radical reforms of current conditions. The British Labour Party and the main European social democratic parties fall within the tradition of democratic socialism, as opposed to Marxism-Leninism. European socialist parties in the twentieth century affiliated within the loose political organizations of the Second International (1889–1916), the International Working Union of Socialist Parties, and the Socialist International (Milliband 1982).

The twentieth century witnessed several important new developments within the intellectual architecture of Marxism. Western Marxism attempted to extrapolate Marx’s ideas in new ways, extending treatment of issues having to do with humanism, dialectics, history, and democracy. Critical theory was an important intellectual elaboration of some of Marx’s philosophical ideas, in the hands of such thinkers as Theodor Adorno (1903–1969), Max Horkheimer (1895–1973), Hans-Georg Gadamer (1900–2002), and Jürgen Habermas (b. 1929) (Geuss 1981; Wellmer 1971). In the 1960s Western Marxism developed a distinctive political standpoint on the issues of the day under the banner of the “New Left”: economic inequality within capitalist countries, inequalities within a colonized world, and struggles for independence by countries in the developing world. Partially shaped by a growing awareness of Stalin’s crimes in the 1940s and
1950s, Western Marxists developed the strand of democratic socialism into a full intellectual and political program. Particularly important were contributions by Perry Anderson (b. 1938), E. P. Thompson (1924–1993), Ralph Miliband (1924–1994), and the New Left Review. This body of thought retained the critical perspective of classical Marxism; it gave greater focus to the world historical importance of imperialism and colonialism; and it aligned itself with the interests of developing countries such as Cuba and India.

**MARXISM AS A BODY OF RESEARCH**

The other important dimension of Marxism in the contemporary world is in the area of knowledge and theory. Marx's theoretical and scientific writings are primarily expressed in his economic writings in the three volumes of *Capital* and *Theories of Surplus Value*, and in his historical writings such as *The German Ideology* and *The Eighteenth Brumaire of Louis Napoleon*. Marx's theory of historical materialism maintains that large historical change proceeds as a result of dynamic interaction between the forces and relations of production (roughly, technology and property relations) (Cohen 1978). Marx identifies the economic structure of society (the forces and relations of production) as the key factor that constrains and impels historical transformation across large historical epochs (the slave mode of production, feudalism, capitalism). And he regards other institutions, including institutions of politics and culture, as part of the superstructure of society. These “superstructural” institutions are social arrangements that serve to support and stabilize the development of the economic structure. Another important element of the framework of historical materialism is the theory of class conflict as an engine of historical change. The central conflict in every society, according to Marx, is the economic conflict between owners of property and the propertyless: masters and slaves, lords and serfs, and capitalists and proletarians. Marx also offers a theory of ideology and mystification: the view that the ideas and beliefs that people have in a class society are themselves a material product of specific social institutions, and are distorted in ways that serve the interests of the dominant classes.

Materialism implies that the economic structure of society is fundamental to its historical dynamics. How does this theory work in relation to modern society? Marx advanced a multistranded analysis of the capitalist mode of production in his most extensive work, *Capital*. This account was intended to be rigorous and scientific (Little 1986; Rosdolsky 1977). Marx hoped to succeed in penetrating beneath the surface appearances of the English economy of the nineteenth century, to discover some “laws of motion” and institutional mechanisms that would explain its historical behavior. There are several independent strands of this analysis: a social-institutional account of the specific property relations (capital and wage labor) that defined the material and institutional context of capitalist development; a sociological description of some of the characteristics of the industrial workplace and the industrial city; a historical account of the transformations of traditional rural society that had created the foundation for the emergence of this dynamic system; and a mathematical analysis of the sources and transformation of value and surplus value within this economy. The mathematical theory based on the labor theory of value has not stood the test of time well, whereas the more sociological and institutional core of the framework continues to shed light on how a modern private-property economy functions.

There is no single answer to the question, “What is the Marxist approach to social science?” Instead, Marxist social inquiry in the twentieth and twenty-first centuries represents a chorus of many voices and insights, many of which are inconsistent with others. Rather than representing a coherent research community defined by a central paradigm and commitment to specific methodological and theoretical premises, Marxist social science in the twentieth century had a great deal of variety and diversity of perspectives. There is a wide range of thinkers whose work falls within the general category of Marxian social science and history: E. P. Thompson, Louis Althusser, Jürgen Habermas, Gerald Cohen, Robert Brenner, Nicos Poulantzas, Perry Anderson, Ralph Miliband, Nikolai Bukharin, Georg Lukács, Antonio Gramsci, and Michel Foucault. All these authors have made a contribution to Marxist social science, but in no way do these contributions add up to a single, coherent and focused methodology for the social sciences. Instead, there are numerous instances of substantive and methodological writings, from a variety of traditions, that have provided moments of insight and locations for possible future research.

**THE TWENTY-FIRST CENTURY**

Where do Marx's ideas stand in the early part of the twenty-first century? Several areas of limitation in Marx's social theories have come under scrutiny by theorists and social critics late in the twentieth century. (1) Feminist and cultural critics have argued that Marx's thought is too economistic and exclusively focused on issues of class—thirty ignoring other forms of oppression and domination that exist in modern society, including those based on gender, race, or ethnicity. (2) “Green” socialists have criticized Marx's theory of capitalist development and socialism on the ground that it is deeply pro-growth, in ways that are sometimes said to be at odds with environmental sustainability. (3) Democratic socialists have criticized
Marx’s rhetoric of class politics on the ground that it gives too little validity to the demands of democracy; they have advocated for a much deeper embodiment of the importance of collective self-determination within socialist theory and practice. (4) Marx’s critique of capitalist society emphasizes economic features to the neglect of cultural or ideological forms of domination. Theorists who consider the social role of communications media argue (reminiscent of Gramsci’s writings) that the softer forms of oppression and domination that are associated with television, the Internet, and the instruments of public opinion are at least as profound in the contemporary world as the more visible forms of political and economic domination that Marx emphasized. Here the writings of Stuart Hall (Hall 1980, 1997) and Raymond Williams (Williams 1974, 1977) have been particularly influential.

Notwithstanding these areas of limitation in Marx’s vision, the most central critical theory within Marxism is the demand for human emancipation from forms of exploitation, domination, and alienation that interfere with full, free human development. And these ideas give ample scope for twenty-first century debates and progress.

MARXISM, BLACK

An examination of black Marxism—the marriage between Marxism and “black radicalism”—illuminates the theoretical gaps in the Marxist canon as it relates to non-Western movements and non-Western liberation struggles that speak in the idioms of culture, nationalism, and race. Black Marxists have grappled with the contradictions that emerge when Marxist paradigms are the medium for the articulation of a path to transformation. While theorists have noted the “anti-bourgeois tendencies in black cultures” (Duran 2005, p. 1), many of the Eurocentric assumptions that pervade Marxism are a challenge to the formulation of a black Marxist theory (see Robinson 1983). Whereas Marxism focuses heavily on the activism of a vanguard proletariat, black freedom struggles have revolved around a collective, albeit contested identity shaped by racism. In reaction, black Marxist thinkers have argued for a position that emphasizes “materialism over idealism” and acknowledges the centrality of race in the black experience (Campbell 1995, p. 420).

Marxism is a method of analysis and a theoretical critique that sees capitalism as a system which fosters social divisions. A powerful class-consciousness, specifically among the working class, is considered vital to the oppositional upsurge that Marxism contends is essential to revolution. Cedric Robinson (1983) argued against the Marxist position that the “European proletariat” is the “revolutionary subject of history” (p. 4). He criticized Marxism’s “dismissal of culture” and its theoretical myopia on the issue of race (p. 78). Furthermore, as A. Sivanandan (1977) explained, “Blacks are a class apart, an underclass, a subproleteriat” (p. 339). Thus, for many black intellectuals, race, rather than being an incidental dimension of class, provides a significant subtext for the theorizing of radical change.

Collaborations between Marxists and black radicals in the United States began in the 1920s and 1930s when African Americans became a focus of organizing by the Communist Party. Early black Communists like Harry Haywood helped to elucidate the “Negro Question” and struggled against the assignment of blacks to a “subidiary position in the revolutionary movement” (Haywood 1978, p. 234). At the Sixth World Congress of the American Communist Party in 1928, resolutions were

Daniel Little
passed on the American “Negro Question.” They concluded that African Americans were an “oppressed nation which had the right to self-determination,” and that the Southern “Black Belt” was prime for revolutionary activity (Haywood 1978, p. 268).

Robin Kelley (1990) charted the history of the connections between southern black resistance and the organizing of the Communist Party in 1930s Alabama. According to Kelley, historically black working-class resistance occupied the “margins of struggle,” and even without a specific organizational context, southern African Americans always possessed a “rich culture of opposition” (p. 99). Communist organizers focused their recruitment on agricultural workers and sharecroppers in Birmingham, making the Communist Party in Alabama a “Southern working class black organization” (p. xii). Communists formed sharecropping unions, neighborhood relief committees, and unemployment councils for the city’s poor. In Alabama, Communists opposed race and class oppression as a totality under the banner of “bread and freedom,” and through the newspaper, The *Southern Worker* (Kelley 1990, p. xii).

Later, the Communist Party chose Harlem, New York, as another “concentration point” because it was the epicenter of black protest (Naison 1983, p. xvii). Early black radicalism in 1930s Harlem aligned itself with the traditions of black nationalism and black militancy. Some Communists considered “narrow nationalism” and “back to Africa” ideologies to be reactionary, although others viewed nationalism as a “legitimate trend in the Black Freedom Movement” (Haywood 229, p. 1978). Mark Naison (1983) documented Communist Party activism in Harlem and described how early black Communists were “race men and women” drawn from the ranks of nationalist organizations. In Harlem, Communists organized workers alliances, tenant unions, cultural groups, and legal defense organizations. Harlem was a rich political landscape, with organizations like the Urban League and the NAACP, and the ultranationalism of Marcus Garvey. Within Harlem, socialist ideas were spread through the work of A. Philip Randolph, president of the Brotherhood of Sleeping Car Porters union. His magazine, the *Messenger*, was accused by the U.S. government of promoting “Bolshevik activities among Negroes” (Kornweibel 1998, p. 21). While in socialist and Communist circles the dominant view, shared by Randolph, was that “race was a strategic weapon to dissipate working class coherence,” convergent race and class struggles dominated mass protests of this time (Henderson 1978, p. 148). Even at the height of the black power discourse of the 1970s, African American activists like Angela Davis—a member of the Communist Party also affiliated with the Black Panthers—continued to forge connections between class struggle and anticommunism.

Within the African Diaspora, the dialectical method of Marxism proved a useful source of insights for those engaged in anticolonial and postcolonial struggles. Afro Caribbean intellectuals and activists such as Trinidadians C. L. R. James and George Padmore, Guyana native Walter Rodney, and Martinique-born Aime Cesaire merged the tenets of Pan-Africanism, nationalism, “Ngréité,” and Marxism. Padmore, a unionist and founder of the Pan-African Federation, remarked, “Labour in white skin cannot free itself while labour in dark skin is branded” (Padmore 1945, p. 3). Cesaire, however, eventually became disillusioned and resigned from the French Communist Party, saying, “What I desire is that Marxism and communism should serve Black people, and not that Black people should serve Marxism” (Caute 1964, pp. 211). C. L. R. James, a Trotskyite, lauded the independent and dynamic trajectory of black struggles in the United States. He believed that “the Negro people based on their own experiences approach the conclusions of Marxism” (Grimshaw 1992, p. 187). In the 1970s the historian Walter Rodney extolled “a working class oriented definition of Black Power” and contended that the extraction of labor from black people was a cornerstone of capitalism (Fontaine 1982, p. 16). Throughout the 1970s and 1980s, Marxism was an instrumental theory in African-based liberation movements in Angola, Mozambique, and Guinea Bissau. Amilcar Cabral, the revolutionary leader of Guinea Bissau, linked class struggle to anti-imperialism, demonstrating the necessity of “incorporating the proletarian project into the project of national liberation” (Magubane 1983, p. 25). Also, apartheid ideologists in South Africa adopted aspects of Marxist dictum even as they emphasized national and racial identities (see Marx 1992).

Marxism continues to inform the spectrum of black progressive politics, even as Afro-Diasporic intellectuals argue for the autonomy of black liberation struggles and their “organic political perspectives” (James 1992, p. 183). Contemporary black intellectuals urge that a tripartite analysis, stemming from “the nexus of three crucial sites of struggles, community, class and gender, be at the center of Black liberatory projects” (Marable 1997, p. 8). If they adhere to this perspective, social justice movements constituted by black people can remain “avant-garde” formations of contiguous race and class struggles (Duran 2005, p. 3).

MASCULINITY

Masculinity refers to the social roles, behaviors, and meanings prescribed for men in any given society at any one time. As such, it emphasizes gender, not biological sex, and the diversity of identities among different groups of men. Although we experience gender to be an internal facet of identity, the concept of masculinity is produced within the institutions of society and through our daily interactions (Kimmel 2000).

SEX VS. GENDER

Much popular discourse assumes that biological sex determines one’s gender identity, the experience and expression of masculinity and femininity. Instead of focusing on biological universals, social and behavioral scientists are concerned with the different ways in which biological sex comes to mean different things in different contexts. Sex refers to the biological apparatus, the male and the female—our chromosomal, chemical, anatomical, organization. Gender refers to the meanings that are attached to those differences within a culture. Sex is male and female; gender is masculinity and femininity—what it means to be a man or a woman. Whereas biological sex varies very little, gender varies enormously. Sex is biological; gender is socially constructed. Gender takes shape only within specific social and cultural contexts.

PLURAL MASCULINITIES

The use of the plural—masculinities—recognizes the dramatic variation in how different groups define masculinity, even in the same society at the same time, as well as individual differences. Although social forces operate to create systematic differences between men and women, on average, these differences between women and men are not as great as the differences among men or among women.

The meanings of masculinity vary over four different dimensions; thus four different disciplines are involved in understanding gender—anthropology, history, psychology, and sociology.

First, masculinities vary across cultures. Anthropologists have documented the ways that gender varies cross-culturally. Some cultures encourage men to be stoic and to prove masculinity, especially by sexual conquest. Other cultures prescribe a more relaxed definition of masculinity based on civic participation, emotional responsiveness, and collective provision for the community’s needs. What it means to be a man in France or among Aboriginal peoples in the Australian outback are so far apart that it belies any notion that gender identity is determined mostly by biological sex differences. The differences between two cultures’ version of masculinity is often greater than the differences between the two genders.

Second, definitions of masculinity vary considerably in any one country over time. Historians have explored how these definitions have shifted in response to changes in levels of industrialization and urbanization, in a nation’s position in the larger world’s geopolitical and economic context, and with the development of new technologies. What it meant to be a man in seventeenth-century France or in Hellenic Greece is certainly different from what it might mean to be a French or Greek man today.
Masculinity

Third, definitions of masculinity change over the course of a person’s life. Developmental psychologists have examined how a set of developmental milestones leads to differences in our experiences and our expressions of gender identity. Both chronological age and life stage require different enactments of gender. In the West, the issues confronting a man about proving himself and feeling successful change as he ages, as do the social institutions in which he attempts to enact those experiences. A young single man defines masculinity differently than do a middle-aged father and an elderly grandfather.

Finally, the meanings of masculinity vary considerably within any given society at any one time. At any given moment, several meanings of masculinity coexist. Simply put, not all American or Brazilian or Senegalese men are the same. Sociologists have explored the ways in which class, race, ethnicity, age, sexuality, and region all shape gender identity. Each of these axes modifies the others. For example, an older, black, gay man in Chicago and a young, white, heterosexual farm boy in Iowa would likely have different definitions of masculinity and different ideas about what it means to be a woman. Yet each of these people is deeply affected by the gender norms and power arrangements of their society.

Because gender varies so significantly—across cultures, over historical time, among men and women within any one culture, and over the life course—we cannot speak of masculinity as though it is a constant, universal essence, common to all men. Gender must be seen as an ever-changing, fluid assemblage of meanings and behaviors; we must speak of masculinities. By pluralizing the term we acknowledge that masculinity means different things to different groups of people at different times.

GENDER IDENTITY

Recognizing diversity ought not to obscure the ways in which gender definitions are constructed in a field of power. Simply put, all masculinities are not created equal. In every culture, men contend with a definition that is held up as the model against which all are expected to measure themselves. This “hegemonic” definition of masculinity is “constructed in relation to various subordinated masculinities as well as in relation to women,” writes sociologist R. W. Connell (1987, p. 183). As Erving Goffman once described it,

In an important sense there is only one complete unblushing male in America: a young, married, white, urban, northern, heterosexual, Protestant, father, of college education, fully employed, of good complexion, weight, and height, and a recent record in sports. Any male who fails to qualify in any one of these ways is likely to view himself—during moments at least—as unworthy, incomplete, and inferior. (1967, p. 128)

Definitions of masculinity are not simply constructed in relation to the hegemonic ideals of that gender, but also in constant reference to each other. Gender is not only plural, it is also relational. Surveys in Western countries indicate that men construct their ideas of what it means to be a man in constant reference to definitions of femininity. What it means to be a man is to be unlike a woman; indeed, social psychologists have emphasized that although different groups of men may disagree about other traits and their significance in gender definitions, the “antifemininity” component of masculinity is perhaps the single dominant and universal characteristic.

Gender difference and gender inequality are both produced through our relationships. Nancy Chodorow argued that the structural arrangements by which women are primarily responsible for raising children create unconscious, internalized desires in both boys and girls that reproduce male dominance and female mothering (1978). For boys, gender identity requires emotional detachment from mother, a process of individuation through separation. The boy comes to define himself as a boy by rejecting whatever he sees as female, by devaluing the feminine in himself (separation) and in others (male superiority). This cycle of men defining themselves through their distance from and devaluation of femininity can end, Chodorow argues, only when parents participate equally in child rearing.

GENDER AS AN INSTITUTION

Although we recognize gender diversity, we still may conceive masculinities as attributes of identity only. We think of gendered individuals who bring with them all the attributes and behavioral characteristics of their gendered identity into gender-neutral institutional arenas. But because gender is plural and relational, it is also situational: What it means to be a man varies in different institutional contexts, and those different institutional contexts demand and produce different forms of masculinity. “Boys may be boys,” writes feminist legal theorist Deborah Rhode, “but they express that identity differently in fraternity parties than in job interviews with a female manager” (Rhode 1997, p. 142). Gender is thus not only a property of individuals, some “thing” one has, but a specific set of behaviors that are produced in specific social situations. Thus gender changes as the situation changes.

Institutions are themselves gendered. Institutions create gendered normative standards and express a gendered
institutions, and are major factors in the reproduction of gender inequality. The gendered identity of individuals shapes those gendered institutions, and the gendered institutions express and reproduce the inequalities that compose gender identity. Institutions themselves express a logic—a dynamic—that reproduces gender relations between women and men and the gender order of hierarchy and power.

Not only do gendered individuals negotiate their identities within gendered institutions, but also those institutions produce the very differences we assume are the properties of individuals. Thus, “the extent to which women and men do different tasks, play widely disparate concrete social roles, strongly influences the extent to which the two sexes develop and/or are expected to manifest widely disparate personal behaviors and characteristics” (Chafetz 1980, p. 112). Different structured experiences produce the gender differences that we often attribute to people (Chafetz 1980).

For example, take the workplace. In her now classic work Men and Women of the Corporation (1977), Rosebeth Moss Kanter argued that the differences in men’s and women’s behaviors in organizations had far less to do with their characteristics as individuals than with the structure of the organization itself and the different jobs men and women held. Organizational positions “carry characteristic images of the kinds of people that should occupy them,” she argued, and those who do occupy them, whether women or men, exhibited those necessary behaviors (Kanter 1977, p. 21). Though the criteria for evaluation of job performance, promotion, and effectiveness seem to be gender neutral, they are, in fact, deeply gendered. “While organizations were being defined as sex-neutral machines,” she writes, “masculine principles were dominating their authority structures” (p. 241). Once again, masculinity—the norm—was invisible (Kanter 1975, 1977). For example, secretaries seemed to stress personal loyalty to their bosses more than did other workers, which led some observers to attribute this to women’s greater level of personalism. But Kanter pointed out that the best way for a secretary—of either gender—to get promoted was for the boss to decide to take the secretary with him to the higher job. Thus the structure of the women’s jobs, not the gender of the job holder, dictated their responses.

Sociologist Joan Acker has expanded on Kanter’s early insights and has specified the interplay of structure and gender. It is through our experiences in the workplace, Acker maintains, that the differences between women and men are reproduced, and in this way the inequality between women and men is legitimated. Institutions are like factories, and one of the things that they produce is gender difference. The overall effect of this is the reproduction of the gender order as a whole (see Acker 1987, 1988, 1989, 1990).

Institutions accomplish the creation of gender difference and the reproduction of the gender order through several gendered processes. Thus, “advantage and disadvantage, exploitation and control, action and emotion, meaning and identity, are patterned through and in terms of a distinction between male and female, masculine and feminine” (Acker 1990, p. 146). We would err to assume that gendered individuals enter gender-neutral sites, thus maintaining the invisibility of gender-as-hierarchy, and specifically the invisible masculine organizational logic. At the same time, we would be just as incorrect to assume that genderless “people” occupy those gender-neutral sites. The problem is that such genderless people are assumed to be able to devote themselves single-mindedly to their jobs, to have no children or family responsibilities, and perhaps even to have familial supports for such single-minded workplace devotion. Thus, the “genderless” job holder turns out to be gendered as a man.

Take, for example, the field of medicine. Many doctors complete college by age twenty-one or twenty-two, and medical school by age twenty-five to twenty-seven, and then face three more years of internship and residency, during which time they become exceptionally busy. Long work periods are common, and the job holder who can balance pregnancy and motherhood with their medical training is rare. For example, in a typical academic career a scholar completes a PhD about six to seven years after the BA, roughly by age thirty, and then begins a career as an assistant professor with six more years to earn tenure and promotion. This is usually the most intense academic work period of a scholar’s life and also the most likely childbearing years for professional women. The tenure clock is thus set to a man’s rhythms—not just any man, but one with a wife to relieve him of family obligations as he establishes his credentials. To academics struggling to make tenure, it often feels that publishing requires that family life perish.

In another example, in a typical academic career a scholar completes a PhD about six to seven years after the BA, roughly by age thirty, and then begins a career as an assistant professor with six more years to earn tenure and promotion. This is usually the most intense academic work period of a scholar’s life and also the most likely childbearing years for professional women. The tenure clock is thus set to a man’s rhythms—not just any man, but one with a wife to relieve him of family obligations as he establishes his credentials. To academics struggling to make tenure, it often feels that publishing requires that family life perish.

Embedded in organizational structures that are gendered, subject to gendered organizational processes, and evaluated by gendered criteria, then, the differences
between women and men appear to be the differences solely between gendered individuals. When gender boundaries seem permeable, other dynamics and processes can reproduce the gender order. When women do not meet these criteria (or, perhaps more accurately, when the criteria do not meet women’s specific needs), we see a gender-segregated workforce and wage, hiring, and promotional disparities as the “natural” outcomes of already present differences between women and men. It is in this way that those differences are generated and the inequalities between women and men are legitimated and reproduced.

“DOING” GENDER

There remains one more element in the sociological explanation of masculinities. Some psychologists and sociologists believe that early childhood gender socialization leads to gender identities that become fixed, permanent, and inherent in our personalities. However, many sociologists disagree with this notion today. As they see it, gender is less a component of identity—fixed, static—that we take with us into our interactions and more the product of those interactions. In an important article, “Doing Gender,” Candace West and Don Zimmerman argued that “a person’s gender is not simply an aspect of what one is, but, more fundamentally, it is something that one does, and does recurrently, in interaction with others” (1987, p. 140). We are constantly “doing” gender, performing the activities and exhibiting the traits that are prescribed for us.

Doing gender is a lifelong process of performances. As we interact with others we are held accountable to display behavior that is consistent with gender norms, at least for that situation. Thus consistent gender behavior is less a response to deeply internalized norms or personality characteristics and more a negotiated response to the consistency with which others demand that we act in a recognizable masculine or feminine way. Gender is not an emanation of identity that bubbles up from below in concrete expression; rather, it is an emergent property of interactions, coerced from us by others.

Understanding how we do masculinities, then, requires that we make visible the performative elements of identity, and also the audience for those performances. It also opens up unimaginable possibilities for social change, as Suzanne Kessler points out in her study of “intersexed” people (hermaphrodites, those born with anatomical characteristics of both sexes or with ambiguous genitalia):

If authenticity for gender rests not in a discoverable nature but in someone else’s proclamation, then the power to proclaim something else is available. If physicians recognized that implicit in their management of gender is the notion that finally, and always, people construct gender as well as the social systems that are grounded in gender-based concepts, the possibilities for real societal transformations would be unlimited. (Kessler 1990, p. 25)

Kessler’s gender utopianism raises an important issue. In saying that we “do” gender we are saying that gender is not only something that is done to us. We create and recreate our own gendered identities within the contexts of our interactions with others and within the institutions we inhabit.

MASCULINITY STUDIES

*Masculinity* refers most commonly to socially constructed expectations of appropriate behaviors, beliefs, expressions, and styles of social interaction for men in a culture or subculture at a given time. The substantive meanings associated with masculinity are culturally specific, and refer to social arrangements and institutionalized practices as well as individual actions and embodiments. Historically, these meanings have been premised on ideologies and symbolism that cast women as “opposite” and inferior to men, and that position some men as superior to other men. This is due, in large part, to the framing of gender expectations by dominant groups in ways that endorse dominant group practices—and the personal characteristics that presumably represent the embodiment of those practices—while at the same time devaluing the practices and characteristics of other out-groups. Evelyn Nakano Glenn (2002) and Eduardo Bonilla-Silva (2001) explain, for example, that Anglo or white men in industrialized Europe, North America, and other parts of the world support practices and social constructs that endorse their own position as superior to nonwhite men and men with little or no material resources.

Despite its complexity and relational character, popular conceptualizations continue to view masculinity narrowly as a unified set of personal characteristics, behaviors, and beliefs—including physical strength, assertiveness, emotional detachment, competition, and the belief that men are better suited than women for positions of leadership and decision making. Though unsupported by scientific evidence, many also believe that masculinity is derived from biology. The notion of essential differences between men and women, and corresponding notions of women’s and men’s different abilities and proclivities, has its origins in late nineteenth-century political movements in Western Europe and the United States. As more women joined the struggle for basic human rights, such as the right to vote and the right to own land, white male scholars focused increasing attention on notions of biological sex difference as a means for supporting ideologies of female inferiority (Carrigan, Connell, and Lee 1985; Fausto-Sterling 2000; MacInnes 2001). Men already in positions of power and privilege relative to women, men of color, men with fewer material advantages, noncitizens, and the disenfranchised, used ideologies of innate differences to justify discriminatory laws and practices (Glenn 2002).

The highly visible women’s movement, as well as the loss of control and opportunity that many men—particularly white men—were experiencing as industrial work processes became more routine and competition for work from immigrants and migrant workers became more intense (Glenn 2002; Kimmel 1996; Roper 1994), also fed into a perceived “crisis of [white] masculinity” in both Europe and the United States at the beginning of the twentieth century (Chauncey 1985; D’Emilio and Freedman 1988). The perception of crisis added fuel to the search for biological evidence of male superiority and white racial superiority (Fausto-Sterling 2000, p. 156; hooks 2004).

Biologically based explanations for sex differences, notes François Nielsen (1994), were pervasive by the mid-twentieth century, and persist still. The logic behind these arguments is that evolutionary processes produce two distinct categories of humans, one that is more physically aggressive, competitive, emotionally independent, and instrumentally decisive, and another that is more passive, cooperative, interdependent, and nurturing. Persons categorized as male are assumed to fit the former, and those categorized as female to fit the latter. Scientific studies reveal many problems with the assumption that biology produces opposite sexes, that gender differences are derived from biology, and that males are innately superior to females. For example, the characteristics and traits that are supposed to differentiate women and men have much more in common than not (Fausto-Sterling 2000; Kemper 1990; Kessler and McKenna 1978).

EARLY VIEWS ON MASCULINITY AS IDENTITY

Not all scholars of the early twentieth century viewed masculinity as a direct function of biology. The foundations of masculinity as identity were established in the early 1900s with the work of Sigmund Freud (1905, 1923). Freud posited that the personality people most commonly associate with masculinity results from complex processes of unconscious conflict resolution and emotional development that start early in life. “The outcome of the differently structured Oedipal crises,” explains Raewyn Connell, “are the bases of Freudian accounts of femininity and masculinity” (1987, p. 204). Freud’s work has been variously elaborated by gender scholars. Nancy Chodorow (1978) focuses on how the division of labor within the family shapes how females and males process unconscious motivations and repressed desire. Given a gendered division of labor in industrial capitalist Western society, explains Chodorow, and a nuclear heterosexual family with a male primary wage
earner, young boys construct a sense of self in relation to a mother figure whose presence is consistent and intense, and a father figure that is more distant because of his role in paid labor. This arrangement leads infants to associate the mother with the fulfillment of desires. Boys' emotional attachment to the mother, however, transforms from one of oneness with her to a form of individuality-with-attachment that is intensely possessive. These possessive feelings for the mother lead the boy to view the father as a competitor for the mother's affections (Di Stefano 1991, pp. 45–48). The feelings of threat that the boy experiences in relation to the father (castration anxiety), along with the need to establish self and not-female, evoke ambivalence, which in turn requires that the boy identify with the father. And to develop a sense of self apart from mother, the boy seeks to establish himself as that which women/females are not (Chodorow 1978, pp. 96–97; Parsons 1964). Emotional detachment, competitiveness, and desire to control self and others become central to his identity (Gilligan 1982; Messner 1992).

Other theorists point out that psychoanalytic object relations views, such as Chodorow's, posit an overly unified concept of self and identity. Connell (1987, 1995) argues that Freud did not assert that processes of personality development produce two clear-cut, stable categories of personality characteristics. Connell agrees that fear of castration at the hands of the father leads boys to repress erotic feelings for the mother, to identify with the powerful father figure, to internalize prohibitions against desire for the mother, and to develop a strong superego, but argues that these are not fail-safe or immanent steps (Connell 1987, p. 204). Many contingencies and conflicts characterize these processes.

Building on existential psychoanalytic theory, Connell proposes the concept of gender projects, which views gender not as a fixed identity but rather as "a system of symbolic relationships" (1995, p. 20). From this view, past attachments, though often repressed, have consequences for future actions. The emotional contradictions and conflicts that arise as a boy goes through the pre-Oedipal and Oedipal stages produce a range of possible outcomes for the individual. The many conflicting emotions that a boy experiences in the development of his sense of self will influence how he projects himself into the future, and thus, the position he takes up in the symbolic order (Connell 1987, p. 211). Boys' and men's gender projects take many forms, some of which are consistent with dominant ideals of masculinity, and others of which are not. "The point," argues Connell, "is that no one pattern of development can be taken as universal even within the specific social context Freud studied" (Connell 1987, p. 206). Not all boys and men take up the same gender project (Chen 1999; Collinson 2003; Majors and Billson 1992; Messerschmidt 2000).

SOCIALIZATION THEORIES AND MASULINITY AS GENDER ROLE

The most common social science frameworks for understanding masculinity since the mid-twentieth century have been sex role (later referred to as gender role) and socialization theories. The concept of sex roles was popularized in the work of Talcott Parsons (Parsons 1964; Parsons and Bales 1955). Underlying the logic of masculinity as a role is the assumption that significant differences separate men from women as social actors. According to Parsons, structural differentiation is a requirement of society, and the division of labor within the family between "instrumental" men and "expressive" women was necessary to ensure proper socialization of children. Boys are also taught within the family, peer groups, schools, and other social organizations and institutions the behaviors and traits that are considered appropriate for boys and men. Boys internalize gender-specific, "appropriate" personalities and behaviors as a result. Masculinity is the identity that corresponds with the position (or role) of man in societal structures.

Modeling behaviors and the rewards and punishments boys receive for their actions facilitate socialization processes. Cognitive approaches to gender socialization posit, further, that once boys embrace the male sex category for themselves, they actively seek activities, behaviors, and modes of presentation that facilitate feedback from others that affirm maleness (Kohlberg 1966). Social cognition models assume that in order to manage the wealth of information to which individuals are exposed in daily life, they look for ways to effectively prioritize the inputs to which they must pay the most attention, which in turn leads to the use of social categories for organizing the social world. Sex categories and corresponding gender schemas, or cognitive structures that allow individuals to organize social information about self and about groupings of people in society, shape what individuals pay attention to, remember, and expect of themselves and other people (Bem 1983, 1993). From this view, prevailing stereotypes about and expectations for men and women in society persist in large part because they provide cognitive road maps and a sense of ontological security for people (Howard and Hollander 1997, p. 88).

One critique of socialization theories is that they equate masculinity with that which men in the most powerful positions in society do (Howard and Hollander 1997; Smiler 2004). By assuming that "normal" males internalize "normative" masculinity, this perspective removes the issue of structural power from the analysis of gender (Connell 1987; Gerson and Peiss 1985; Lopata and Thorne 1978). Boys and men who fail to follow these prescribed paths are thus viewed as deviant (Schur 1984). Socialization is cast as an explanation without explicit dis-
cussion of the power struggles between differently empowered social groups (Howard 1988; Howard and Hollander 1997).

Socialization and role theories, in addition, reify the notion of gender dualisms, thereby minimizing and obscuring differences between men and other men, and between women and other women, and fail to address the intersections of social categories of difference and inequality—such as class, race, and sexual orientation—and how these shape negotiations of dominant masculinity imperatives (Chen 1999; Collinson and Hearn 1994; Martin 1996; Nonn 2004). The notion that masculinity exists as a “role” into which boys and men are socialized obscures how power structures mediate individual negotiations of identity and self.

Throughout U.S. history, for example, boys and men of color have resisted many of the practices and beliefs constructed by white and middle- to upper-class men as appropriate and ideal for “true” men, especially those practices and beliefs that cast men of color as inferior. Men oppressed by other men on the basis of race, ethnicity, and national origin have approached power hierarchies and the men whose positions of structural power enable them to mobilize resources in their own favor with what the American educator and writer W. E. B. Du Bois (1903) identified as “double consciousness.” Double consciousness is born out of the experience of being constrained not by actual personal inequalities but by structures and practices constructed and reinforced by those who control material and symbolic resources. This two-sided consciousness allows members of systematically subordinated groups to understand the dominant group’s constructions of status differences and related expectations for social behavior while at the same time resisting the dominant culture’s construction of the subordinated group as inferior. The notion that masculinity exists as a role that boys and men fit to varying degrees, however, backgrounds the continual negotiations among men and between women and men over the actual meanings that constitute what is commonly referred to as masculinity.

**MASCULINITIES, HEGEMONIC MASCULINITY, AND GENDER AS RELATIONAL**

The limitations of identity and role theories of gender have led many late twentieth- and early twenty-first-century scholars to argue that masculinity does not consist of a single unified set of practices, beliefs, or characteristics. Rather, masculinities are multiple and exist not only as embodied practices, characteristics, and beliefs, but also as routinized and institutionalized practices and symbols. As such, masculinities are constructed and negotiated via discourse and material relations, and are the object of contestation by groups and individuals (Carrigan, Connell, and Lee 1985; Collinson and Hearn 1994; Hearn 1998; Whitehead 2002). This scholarship emphasizes the relational and hierarchical character of socially constructed genders (Connell and Messerschmidt 2005; Collinson and Hearn 1994; Martin 2001; Whitehead 2002).

Gender as a relational concept acknowledges that while bodies are sex-differentiated (i.e., they produce some different physiological needs), these differences do not determine the actual practices in which people engage. Instead, social embodiment transforms bodies (Connell 2002, p. 50). Masculinities and femininities are sets of practices constrained but not fully dictated by “the structure of social relations that centers on the reproductive arena” (Connell 2002, p.10). The reproductive arena refers not to a biological base for gender but rather an arena in which social processes occur. Practices exist as patterns of relationships that connect and separate individuals, and constrain the practices in which individuals engage.

Gender as a relational concept also acknowledges the “different material interests that groups have in an unequal society” (Connell 2002, p. 71). Men have less interest in changing the social structures that give them a collective advantage over women and are more invested than women in maintaining the category “woman” as the “other” against which men are defined because this distinction supports the illusion of gender difference and male/masculine superiority (Bordo 1993). Similarly, Anglo and middle- and upper-class men are more invested in maintaining the structures that sustain their collective advantage over oppressed race and ethnic groups, and over lower socioeconomic classes of men (Lewis 2003; MacLeod 1995; Majors and Billson 1992; Willis 1977).

Hegemonic masculinity, the conceptual framework used commonly to express gendered relations of domination and subordination, refers to “the configuration of gender practice which embodies the currently accepted answer to the problem of the legitimacy of patriarchy, which guarantees (or is taken to guarantee) the dominant position of men and the subordination of women” (Connell 1995, p. 77). Hegemonic masculinity is composed of practices that enable and sustain the status and power of men over women collectively (external dimension) and of some men over other men (internal dimension) (Demetriou 2001). All males (and those who pass as male; Halberstam 1998) are subject to prevailing expectations of hegemonic masculinity, though few actually live up to these expectations (Bird 2003; Dellinger 2004; Messerschmidt 2000; Messner 1992). Few men fit hegemonic ideals of masculinity for any extended period because these ideals and standards change over time and vary by social context, and because men’s bodies and minds also change over the life course.
Supporting a family financially, exercising autonomy and authority in paid labor, and superior athleticism are all examples of practices that commonly align with hegemonic masculinity in many contemporary Western nations. Most men support the idea that these are practices that distinguish men as different from and superior to women (and lesser men), and confer legitimacy and status upon men who are exemplars of these practices (Chen 1999; Gerschick and Miller 1994; Henson and Rogers 2001). This is the case even though hierarchies of class, race, ethnicity, sexual orientation, gender expression, religion, and able-bodiedness ensure that not all men exercise the same level of power or status over women. Most men remain complicit with hegemonic masculinity because as long as the category “man” is constructed as distinct from and superior to the category “female,” dominant as well as subordinated men will continue to benefit from the status of being male (Whitehead 2002).

Resistance to and even rejection of hegemonic masculinity imperatives does, however, exist (Gerschick 1998; Majors and Billson 1992). Thomas Gerschick explains, for example, that while some men with physical disabilities embrace fully ideals of masculinity that only fully able-bodied men can attain, others reject these ideals and construct meanings of their own. Whether and the extent to which one embodies hegemonic practices is partly a matter of having the resources to do so, partly a matter of being allowed to embody such practices, and partly a matter of wanting to embody them.

Research also shows, however, that while there are many forms of resistance to hegemonic ideals and imperatives of masculinity (Boyd 1997; Garcia 2004; Majors and Billson 1992; Mirandé 1997; Neal 2005), complete rejection of all elements of hegemonic patriarchal masculinity is rare (Carby 1998; hooks 2004; Neal 2005). Scholars including Hazel Carby, Anthony Chen (1999), Jerry Garcia (2004), bell hooks (2004), and Mark Anthony Neal demonstrate, for example, how African American, Latino, and Asian American men often adopt patriarchal sexism even as they are struggling against white men for racial and ethnic equality.

Since the 1990s, scholarship has examined the themes outlined above in a variety of contexts, including work organizations (Bird 2003; Britton 2003; Dellinger 2004; Kerfoot and Knights 1993, 1998; Martin 1996, 2001; Pierce 1995; Williams 1995), families (Adams and Coltrane 2005; Marsiglio and Pleck 2005), sports (Messner 1992, 2004), crime and violence (Messerschmidt 2000), the media (McKay, Mokosza, and Hutchins 2005), education (Ferguson 2000; Lewis 2003; McGuffey and Rich 1999; Swain 2005), and leisure settings (Bird 1996; Bird and Sokolofski 2005; Campbell 2000). Gender theorists have called for a greater focus beyond the level of organizations, institutions, and cross-cultural comparative ethnographies. Scholars, including Sikata Banerjee (2005), Wendy Bracewell (2000), Charlotte Hooper (1998, 1999), Joane Nagel (1998, 2005), Raewyn Connell (2005), and Sergei Zherebkin (2006), illuminate macro constructions of masculinity and the relationships between nationalism, imperialism, and globalization. Nations seeking to construct and/or sustain national unity, loyalty, and strength, especially military strength, draw upon the imagery, power relations, division of labor, and emotional relations associated with emerging global patterns of hegemonic masculinity. While Connell (2005) argues that an emerging global hegemonic masculinity focuses on transnational business practices, Hooper (1999) asserts that practices in the arena of international power politics are the basis for a global hegemonic masculinity. These and other scholars note the need for further collaborations across continents and nations in the study of masculinities (Committee for Research on Men and Masculinities in Europe 2005; Gutmann and Viveros Vigoya 2005; Morrell and Swart 2005; Taga 2005).

EVOLVING SCHOLARSHIP

In this brief overview, some of the key theoretical issues regarding the study of masculinities have been presented. During the twentieth century, scholarship moved away from theories that posit biological determinism and toward a greater understanding of masculinities as social constructs that exist not simply as personality characteristics but as practices that are variously taken up by individuals and, at the same time, are embedded in organizations, institutions, and global systems. Twenty-first-century scholars study multifaceted “masculinities” that, in conjunction with multifaceted “femininities,” organize every aspect of social life.

MASLOW, ABRAHAM

1908–1970

Abraham Harold Maslow, often referred to as the “father of humanist psychology,” was born in Brooklyn, New York, on April 1, 1908. He was the first of seven children born to Jewish immigrants from Russia. Maslow completed his BA, MA, and PhD, all in psychology, at the University of Wisconsin. After graduating, he held various academic positions, spending the bulk of his career at Brandeis University in Waltham, Massachusetts. Maslow served as the chair of the Brandeis Psychology Department from 1951 until 1969. An avid researcher, lecturer, and writer, he published extensively, authoring more than thirty-one articles and eight books. Maslow died of a heart attack at the age of sixty-two on June 8, 1970. His work remains among the most influential in humanist psychology and enjoys continued recognition and application in myriad disciplines, including education, marketing, management, psychology, sociology, and communications.

Maslow is best known for his *hierarchy of human needs*, first proposed in 1943 in “A Theory of Human Motivation.” In the original paper, Maslow concluded that humans have five sets of basic needs:

*Physiological needs*: These are the most basic of all human needs and include air, food, shelter, water, sex, and sleep.

*Safety needs*: This need category includes physical and psychological safety. Issues of personal safety and security of family, property, and employment are all included.

*Love needs*: Although Maslow originally labeled this as *love*, later interpretations expanded the notion and renamed it *belongingness*. Maslow stated that all individuals desire affection and a sense of belonging.

*Esteem needs*: Maslow argued that all individuals have a need for self-respect and the respect of others. This need category was divided into two subsidiary sets: (1) the need for strength, achievement, and adequacy; and (2) the desire for reputation and prestige, recognition, attention, and appreciation.

*The need for self-actualization*: Maslow described this as the need for individuals to do what they were meant to do, and argued that individuals could not be truly satisfied unless they became all that they were capable of becoming. He noted that a singer must sing and a poet must write if they are to be truly healthy and happy.

Maslow argued that these needs are arranged in a hierarchy of prepotency, and that individuals are motivated to fulfill lower-level needs before they are motivated to fulfill higher-level needs. For example, an individual experiencing thirst will be motivated to satisfy that need before other (higher) needs are considered. Once all phys-
iological needs are met, the individual will be motivated by safety needs. According to Maslow, the four lowest levels are deficiency needs, and the top level is a growth need.

Most modern-day depictions of Maslow’s hierarchy place the five levels of needs in a triangle or pyramid formation, with the lowest level of needs (physiological) at the bottom and self-actualization at the top. In many texts, this is all we see of Maslow’s work, and his name has become almost synonymous with the motivation triangle.

Despite the widespread use and adaptation of Maslow’s hierarchy of needs, it is not without its critics. Much of the criticism lies in the lack of empirical support for the hierarchy. Other criticisms stem from the methods used in Maslow’s research, citing small sample sizes and “pseudoscientific” methods. Maslow himself argued that his theories were overused and understudied. In his personal journals, he wrote about limitations of reliability, validity, and small sample sizes and urged people to replicate his research to address these issues. Despite these criticisms, the hierarchy still holds a prominent place in motivation theory and can be found in many university textbooks. Many new theories of motivation have been introduced since Maslow’s work was completed. Although these theories claim better reliability and validity, and have more empirical support, Maslow’s conceptualization of a needs-based theory of motivation lies at the core of many of the new theories.

The hierarchy of needs is but a small sample of Maslow’s contribution. Although best known for his work on the hierarchy of needs, Maslow was much more concerned with moving members of society beyond the basic needs, through self-actualization, to a more enlightened existence that he called eupychia. Maslow’s work also offered insights into leadership theory, psychotherapy, organizational change, dominance and sexuality, and the meaning of work. Influenced by such great thinkers as Sigmund Freud (1856–1939), Karl Marx (1818–1883), Kurt Goldstein (1878–1965), Alfred Adler (1870–1937), Erich Fromm (1900–1980), and Karen Horney (1885–1952), Abraham Maslow’s contribution to humanist psychology is undeniable. Indeed, many credit him with founding the “third force” of psychology, following on the heels of the behaviorism and psychoanalytic schools of thought.

MATERIAL CULTURE

Material culture consists of any physical manifestation or product of culture. Culture as a conceptual category exists in opposition to material culture, with culture sometimes distinguished as mental culture or nonmaterial culture, although some scholars take issue with such a Cartesian distinction. Alternatively material culture can be taken as a subset of a primary category, culture. Following the gist of E. B. Tylor’s ([1871] 1974) classic 1871 definition, culture, in social science usage, comprises a complex whole of patterned knowledge and behavior; that which is traditional but also emergent, cumulated, learned, and acquired by members of society. By the mid-twentieth century culture could be defined and understood in literally hundreds of ways (Kroeber and Kluckhohn 1952); by the late twentieth century the term had been deconstructed by some postmodernist thinkers as totalizing, hegemonic, essentialist, and an imagined figment. Tylor employed the term material culture as early as 1871, although he apparently neglected to define it (Reynolds 1987, p. 155; for a commentary on the concept, see Buchli 2002, pp. 2–8).

Culture resides in the mind and is shared across minds. Material culture renders culture manifest in physical, palpable, measurable form. For archaeologists, folklorists, historians, museum curators, and others, material culture evidences the cultural. Material culture includes what archaeologists typically refer to as artifacts, collectors as relics, and art historians as objets d’art. Artifacts include such objects as stone tools, potsherds, bottles, beads, but-
tons, fibulae, coins, clay pipes, paintings, and textiles. To this list of conventionally recognized artifacts one should add such large-scale examples of material culture as buildings, monuments, gardens, gravestones, watercraft, roads, bridges, tunnels, dams, irrigation ditches, fences, wharves, landfills, and landscapes—all part of the intentionally built environment. For some scholars, any modification of the environment resulting from cultural activity, deliberate or not, counts as material culture: trash middens, oil spills, crop marks, cultigens, particulate emissions, food bones, human skeletal remains, manuports (materials moved out of their original location by human agency, like moon rocks brought to earth), and ecofacts of all sorts and conditions (such as flower pollen in Neanderthal burials or oyster shells filling in a road pothole). All writing and symbolic expression, from pictographs, graffiti, iconography (Munn 1973), and tattoos to cuneiform tablets and comic books can be considered material culture. The anthropologist and archaeologist James Deetz has suggested that spoken language be thought of as material culture in its "gaseous state" (Deetz 1996, p. 36), because sounds physically set air in motion during speech, if only briefly. Whether or not one wants to go so far as to accept spoken language as material culture, one can certainly admit records, tapes, and DVDs.

Material culture—past and present, partial and entire, in situ at an archaeological dig, on or of the landscape, or cached in a museum—illuminates cultural phenomena in many ways. Material culture communicates, expresses meaning, conveys experience, disciplines, and exhibits agency. Just as material culture is various, so too the study of material culture reflects a broad array of perspectives, analytical stances, and underlying philosophical traditions.

DESCRIPTION
Description remains foundational to material culture studies. The anthropologist Franz Boas ([1888] 1964), in one of the first formal ethnographies, recorded material as well as nonmaterial culture by describing such items as igloos, harpoons, and dolls, which were illustrated with sketches. For archaeologists, time, space, and form constitute three important descriptive dimensions of material culture. It is essential to know how old an object is and when it was used, recycled, or discarded. Chronology supplies part of the crucial cultural context of material culture. Dozens of dating methods yield relative and absolute chronologies. Relative dating, which establishes that something is older than, newer than, or contemporaneous with something else, is exemplified by cross dating derived from stratigraphy and an examination of stylistic change. Absolute dating methods, which assign age in calendar years, include obsidian hydration, dendrochronology (using tree rings), and radiometric techniques such as radiocarbon dating.

It is also invaluable to know an object’s spatial location—its point of origin or place of discovery. Provenance, like chronology, constitutes prime contextual data. Location might be variously logged as a cultural area, city, or country name, an archaeological excavation’s grid/stratification, or a set of latitude and longitude points in a geographical positioning system. Lack of provenance is problematical because it means spatial context has been lost.

Form involves the attributes or characteristics of an object. Description of form entails acquiring and recording data concerning factors such as dimension, color, texture, chemical composition, and stylistic elements. Taxonomy, typology, or classification may draw on numerous methods, such as the type-variety concept, modal analysis, numerical taxonomy, and linguistic models. The widely applied type-variety approach identifies configurations of associated attributes to generate categories of types and varieties. In modal analysis, single attributes such as stylistic motifs can be traced through time and space. Numerical taxonomy codes for multiple attributes and tests for clustering or correlations by means of statistical routines. Typology based on linguistic models posits parallels to language, using either constituent units analogous to phonemes or morphemes or a set of grammatical rules for object construction. The results of typological analysis end up in such formats as exhibit catalogs, databases, museum labels, and archaeological site reports.

TECHNOLOGY AND FUNCTION
Considerations of technology and function are vital to material culture studies. Some typologies, such as the first ones developed in the second half of the nineteenth century to describe European Paleolithic assemblages, posit functions for stone tools, such as scraper, grauer, and burin. The approach known as experimental archaeology (see Coles 1973; Reynolds 1979; Gould 1980; Ingersoll, Yellen, and Macdonald 1977) features rigorous testing of technology and function, applied to areas as diverse as flint-tool knapping and the experience of building and living in an Iron Age village. To discover aspects of technology or function, sophisticated laboratory analysis may be performed, as was the case with Arlene Fraikor et al. (1971), who showed that the copper in Hopewell earspools (Ohio, c. 100 BCE–550 CE) was shaped both by annealing and cold hammering. Thomas Loy and James Dixon (1998) contributed to the understanding of the function of 11,000-year-old Alaskan fluted projectile points when they identified species like mammoth, Dall...
sheep, and bison from blood cell residues preserved in the tools’ crevices.

DIFFUSION AND DISTRIBUTION
Some of the earliest material culture studies, conducted during the late nineteenth and early twentieth centuries, focused on the distribution of elements of material and nonmaterial culture. The British heliocentric diffusionist school of Grafton Elliot Smith and William J. Perry and the German/Austrian diffusionist school of Friedrich Ratzel, Fritz Graebner, Leo Frobenius, and Wilhelm Schmidt identified complexes or culture circles of material and nonmaterial culture traits and used migration and borrowing to account for cultural differences. Similarly the twentieth-century American anthropologists A. L. Kroeber ([1939] 1952), Clark Wissler (1914), and Harold Driver (1961) linked cultural traits—with material items figuring prominently—to geographical areas, yielding culture areas. Nonmaterial elements like kinship terminology and language were combined with material culture categories, such as housing types, crafts, and art, and were mapped across culture areas. Material items from the Arctic culture area, for example, might include igloos, kayaks, and ivory tools. The culture area approach still finds expression (Kehoe 2006) as an organizational principle for ethnological surveys. One notable continuation of diffusionist analysis is the early work of the folklorist Henry Glassie (1968), which, in the tradition of the geographer Fred Kniffen, traces the diffusion of vernacular buildings, musical instruments, and tools across the eastern United States. The focus on culture element distributions still finds representation in twenty-first-century cultural and material culture studies in the extensive ethnological and archaeological databases at Yale. Known as the Human Relation Area Files (HRAF), these were initially published in book form but are available on the Web by subscription (http://www.yale.edu/hraf/).

PROCESS
Part of a much larger system, material culture can be viewed as performing certain systemic functions, such as fulfilling human needs or adapting to environmental change. Early twentieth-century functionalism, largely descriptive and static, was somewhat displaced during the 1960s by positivist and processual approaches, often fortified by conflict theory and cultural ecology. Processual archaeology seeks, by means of the hypothetico-deductive approach, to explain relationships within specific cultures as well as the evolutionary record across cultures. In a pioneering study Sally Binford and Lewis Binford (1969) employed factor analysis to relate clusters of tools to climate and environmental change. Susan Kent (1984) compared spatial patterning of domestic activity areas in Navajo, Euro-American, and Spanish American sites in the Southwest. William Rathje and Cullen Murphy (1992) contrasted what people presume to be in urban landfills with what really is there by means of laboratory-based quantification.

HISTORY, ART HISTORY, ARCHITECTURE, AND AMERICAN STUDIES
Many material culture studies simultaneously examine art, folk art, history, and technology. For example, the Winterthur Museum and Country Estate has published numerous books and conference papers on material culture and the decorative arts, examining categories such as clocks, ceramics, glass, furniture, architecture, gardens, and silver. A collection of material culture studies edited by Ian Quimby (1978) illustrates this approach. J. Ritchie Garrison (1991) followed the approach of Fernand Braudel to the local, individual level when he tracked the development of wealth and social status in Franklin County, Massachusetts, through an analysis of crops, architecture, and farmsteads. Robert Thompson and Joseph Cornel (1981) combined field and informant-based data, study of museum collections, and documentary research to decipher the meanings and social context of maboondo, bottomless cylindrical vessels placed on some Ki-Kongo graves (in Zaire) to symbolize the wisdom of deceased leaders. The art historian Thompson finds echoes of this Ki-Kongo tradition in the seashells and mugs with broken-out bottoms found on some African American graves in the southeastern United States.

MATERIAL CULTURE AS COMMUNICATION SYSTEM
Material culture, even when it appears to us as mere technology, communicates. Whatever culture needs or aspires to communicate or signal can be represented or reflected in material culture. Consider material culture as an alternative to spoken language and gesture—a medium less flexible but more enduring (McCracken 1987). Expressions and symbols of social and cultural identity, affiliation, role, rank, wealth, status, age, gender, values, and beliefs constitute a major area of interest for scholars of material culture. Material culture, from this perspective, can be thought of as providing a parallel record of a culture’s worldview, values, and beliefs. A study by the geographer Peter Hugill (1984) showed how material culture can communicate about and correlate with social indicators. Looking at the evolution of the landscape in the Cazenovia area of New York, Hugill revealed ways the old elite maintain status over the newly wealthy by means of a “full range of gestures in the aesthetic-historical-genealogical” complex” (Hugill 1984, p. 29). Among that
range of “gestures” are old homesteads infused with family history, something not readily attained by the newly wealthy. The creaky homes of the old elite proclaim a status beyond the purchasable.

Material culture systems may also be at variance with the nonmaterial, however. For example, language and material culture distributions do not necessarily predict each other (Welsch, Terrell, and Nadolski 1992); likewise, in traditional societies ownership of modern material culture may fail to correlate with values of modernity (Robbins and Pollnac 1974). Furthermore, although material culture exists in a sense as doubly cultural—first as a pattern in minds, second as material representation—not all material culture communications are intentional or even consciously understood. The plain, unadorned cross of the Southern Baptist church and the Christ on the cross of Latin American Catholicism symbolize, respectively, the ethereal (risen) Pentecostal Christ and the earth-bound, suffering Christ (Richardson 2003, p. 122)—but few churchgoers consciously register these theological messages.

**MATERIAL CULTURE AS MEANING AND COGNITION SYSTEM**

One prominent approach to meaning in social science, structuralism, emphasizes patterned cultural meanings and central symbols and focuses on cultural abstraction or culture as knowledge system. By contrast, symbolic interactionism investigates the active behavioral processes of socialization and the realm of social actors. Each yields different pictures when applied to material culture. Inspired by the work of the structuralist anthropologist Claude Lévi-Strauss and the linguist Noam Chomsky, Henry Glassie (1975) analyzed vernacular Virginia houses and deduced a grammar of spatial proportion and function through which symbolic oppositions inherent in Western culture—such as natural/artificial and public/private—were expressed. The anthropologist Claire Farrer (1991) encountered expressions of the Mescalero Apache “base metaphor” throughout Apache culture, including in material forms, such as baskets, the tribal museum’s layout, and the Holy Lodge. Sunwise directionality, circularity, sound and silence, harmony and disharmony, colors, gender, and the number 4 are among the integrated symbolic qualities of the Apache base metaphor. (See Hodder 1982 for a host of structuralist-oriented material culture studies by archaeologists.)

As for the social interactionist perspective, one can point to Rhys Isaac, who, influenced by the sociologist Erving Goffman, conducted a dramaturgical analysis of an eighteenth-century Virginia house “Sabine Hall” and of a diary from the 1760s written by Colonel Landon Carter. From these two sources, Isaac reconstructed webs of social relationships and daily rituals. Sabine Hall and its spaces appear as a stage with props, part of the material “definition of the situation” conditioning social action in eighteenth-century daily dramas. In a similar vein Miles Richardson (1987; see also Low 2000), influenced by the work of Goffman and the philosopher George Herbert Mead, contrasted the preliminary definitions of the situation and socially generated meanings of contemporary markets and plazas in Spanish America and then, guided by the concept of artifact as “collapsed act,” outlined how archaeologists might rediscover the lost social world of a burial mound.

Akin to structuralism and symbolic interactionism is what is sometimes called cognitivism. For cognitivist archaeologists the question is: How did people of the past think? Through inferences drawn largely from the analysis of material culture, archaeologists reconstruct cultural thought processes. At Pincevent and other French sites of the Magdalenian age, C. Karlin and M. Julien (1994) found evidence of stages of “apprenticeship” in regard to lithic stone tool–making ability, which may reveal age and skill-level communication within a system of groups.

**MATERIAL CULTURE AS COMMODITY SYSTEM**

A universal category of human experience, exchange, incorporates material culture in both economic and symbolic ways. The work of two scholars, Igor Kopytoff and Daniel Miller, exemplifies the focus on exchange in material culture studies. If one follows their trajectories, things accumulate their own biographies just as people do, Kopytoff (1986) has suggested. One process Kopytoff has identified, commoditization, brings a wide range of objects into the orbit of one common exchange medium, such as money. But commoditization, as convenient and expansive as it tends to be, may threaten other social interests; hence some objects may undergo the nearly opposite process of singularization in order to be protected from commoditization. An artist’s commoditized painting is bought and sold half a dozen times; after the artist becomes famous, the painting is purchased by a museum and becomes, at least temporarily, singularized.

For his part, Miller challenged the common assumption that globalization is an entirely homogenizing process. In his 1998 study of Coca-Cola in Trinidad, he observed that Coca-Cola furnished only one of several ways of preparing locally defined and preferred “black sweet drinks” (such as rum and Coke). The powerful locally owned distributor of Coca-Cola followed its own strategy—not Coca Cola’s—when it came to marketing.
AGENCY AND POWER

Some analysts treat material culture as taken for granted or received (as with nonmaterial culture). Others, however, see material culture as imbued with the power to direct human thought and behavior or to reinforce class, gender, or other inequalities (McGuire and Paynter 1991). Inverting the Hegelian dialectic, Karl Marx set the stage for the materialist analysis of technology and material culture by proclaiming, “It is not the articles made, but how they are made, and by what instruments, that enables us to distinguish different economic epochs” (Marx [1887] 1967, p. 180). Marx incorporated the evolutionary scheme of Lewis Henry Morgan ([1887] 1985) to extend into prehistory the relations of modes of production, and in the process he provided an enduring model for Soviet archaeology, material culture studies, American cultural materialism (see Harris 1979), and of course numerous versions of conflict theory and critical theory. Continuing in this materialist vein and informed also by the work of Immanuel Wallerstein, Fernand Braudel ([1967] 1973, 1977) has traced the history of evolving relationships, on a worldwide scale, between economics and material culture categories, such as towns, housing, motive power sources (steam engines, water wheels, etc.), food, and money.

In his study of the material culture of seventeenth- through nineteenth-century Annapolis, the archaeologist Paul Shackel (1993) argued that clocks, scientific instruments, and items such as individual dinner plates, knives, forks, and spoons all enforce “discipline” and etiquette systems. At first only owned by the elite, clocks and scientific instruments such as telescopes served to “measure” time. Because it is measured, time can be made to appear as if it exists externally in nature rather than being a human construct; clocks then are used to set discipline parameters for everyday life, such as the beginning of a factory shift or a unit of pay (the hourly wage). Eventually all people come to possess clocks and to conceptualize time as located in nature.

Not all such analysis derives from conflict theory. In his evaluation of New York City public parks and plazas, the sociologist William Whyte (1980) documented the power of spatial layout and architecture to either invite or repel users. Places to sit, sun, shade, and water (in fountains and pools) invite human presence; fences, walls too high to sit on, immovable and uncomfortable benches, or threatening signs repel.

CONTESTED MATERIAL CULTURE

As mentioned in the above discussion of agency, analysts of material culture frequently draw on conflict theory and deconstruction theory (in anthropology the latter is sometimes referred to as post-structuralism). A collection of essays edited by Christopher Tilley (1990) explores ways the work of deconstructionists like Jacques Derrida and Michel Foucault might be applied to archaeology. Deconstruction places social power and systems of control front and center, and not surprisingly, material culture is very much taken into consideration. John Dorst (1989) detailed the properties of postmodern life represented by material culture found in the booths and exhibits of the annual Chadds Ford Days living history fair. As the visitors moved through the exhibits at the fair, observing and purchasing souvenirs, they marked or enacted difference and engaged the fair’s “controlling image” of the late-eighteenth-century domestic sphere. At Chadds Ford the struggle to legitimize and represent the social order manifested itself at several levels: as a competition between the Brandywine River Museum, the Historical Society, and the Chris Sanderson Museum and on the landscape itself, where the projected nostalgic images of the Wyeth school wrestled with the suburban dream.

Courtney Workman (2001) documented the tortured politics surrounding a statue, The Woman Movement, designed by Adelaide Johnson in 1921 and portraying Elizabeth Cady Stanton, Susan Brownwall Anthony, and Lucretia Mott. On display briefly in the rotunda of the Capitol building, it was then removed to a basement closet, where it resided until 1997 in spite of numerous lobbying efforts over the years. The National Political Congress of Black Women sought to block relocation, demanding that Sojourner Truth first be added to an unfinished part of the monument. Even the way material culture is represented by archaeologists to archaeologists may be contested; for example, Janet Spector (1993) attempted to correct the underrepresentation of women’s presence and activities in the archaeological record of a Wahpeton Dakota village.

“EXPERIENCE-NEAR” MATERIAL CULTURE

Material culture can also be presented in a way that is “experience-near,” to use Clifford Geertz’s term—that is, from the perspective of those who create it or experience it firsthand. Folklorist Simon Bronner helps one to encounter the “evidence of tangible things” (1986, p. 1) whether it’s entering a house, making turtle soup, or carving gravemarkers. Henry Glassie’s (1999) sensitive reporting allows one to enter into the mind of Hagop Barin, a Turkish Oriental carpet restorer working in Istanbul and Philadelphia. For Hagop, the good rugs evoke memories, create a mood and a feel. They are not just rugs but works of art with the hearts and thoughts of their creators woven into them.
CONCLUSION

Material culture can be analyzed from many perspectives. Its study is pursued by many disciplines both within and outside of the social sciences: anthropology, archaeology, architecture, art history, folklore/folklife, history, American studies, geography, cultural history, historic preservation, museology, and sociology. What is common to these perspectives and disciplines? For all, material culture serves as the principal source of data (Deetz 1977, p. 10). Material culture is habitually contrasted and related to nonmaterial culture. Space/time/culture boundaries are relaxed and transcended, such that material culture from any time, place, or culture becomes an object of interest. The focus is on comprehending material culture for its cultural and social significance, not on objects as things to be assessed, possessed, or appreciated. Material culture constitutes a "supercategory of objects," to apply differently a term employed by Victor Buchli (Buchli 2002, p. 6). Surprisingly, even as disciplines, schools, and perspectives proliferate, those studying that supercategory of objects, material culture, appear to readily cross disciplinary lines and read and cite each other's work (see Lubar and Kingery 1993; Miller 1998; Reynolds and Stott 1987; Richardson 1974; Schlereth 1982).

**MATERIALISM**

Materialism is a philosophical doctrine of existence that argues that human consciousness is determined either principally or exclusively by matter and its change or manipulation. This “primacy” of matter has its foundation in an early philosophical argument that while material being (or the body) can exist without the mind, the mind is unable to exist without corporeality. Because materialism in its most basic and unifying sense as a doctrine relies on the denial of the nonmaterial (and thus a mechanistic relationship between the nature and its manipulation), many view it as quite different from other conceptualizations of existence (or ontologies) that analyze the relationship between entities such as mind, body, and spirit. It is seen
rather as a philosophical assertion in juxtaposition to a
doctrine of idealism, and in particular its invocation of the
supernatural or disembodied existence. Later forms of
materialism proved far less reductionist with respect to the
mind and subjective experience; still, at its most basic,
materialism implicitly denies the possibly of any Cartesian
mind/body dualism, as processes of the mind are subordi-
nated to the physical environment in which they must take
place, and not to some disembodied realm of existence.

Questions of materiality are among the oldest of
philosophical inquiries. Epicurus and Democritus, the
Greek philosophers on whom the noted historical materi-
alist Karl Marx based his doctoral thesis, were among the
earliest thinkers to expound a metaphysical doctrine of
materialism. Early forms of materialism sought to explain
human experience in terms of how atoms interacted with
one another in nature to manifest different objects. This
type of thinking was opposed to that of some of their
Hellenic contemporaries (notably Plato and Aristotle)
who proposed the existence of immateriality. It is the
implicit denial of a spirit or otherworldly embodiment of
the mind in these early forms of materialism that has led
many to argue that materialism is an intrinsically atheistic
philosophy. This point about the tension between religion
and intellectual inquiry is significant, because material-
ism’s emergence as a significant doctrine occurred as a
product of Enlightenment questions about the role of sci-
ence and religion in social life.

MATERIALISM: SCIENTIFIC VERSUS
DIALECTIC

Materialism has had a propensity for misrepresentation as
teleological and deterministic philosophical doctrine,
wherein critics warn of insinuations that matter is being
afforded a kind of unmediated rationality in guiding
action and history. This is in part attributable to a misun-
derstanding of the major philosophical and social scient-
fic debates that have taken place since the introduction
of the concept of dialectics in the nineteenth century. A
common error, for instance, rests on characterizing Marx’s
historical materialism (a term in fact coined by Friedrich
Engels) as such by referencing his introduction to his
Contribution to a Critique of Political Economy (1859), in
which he concludes that legal and political superstructures
arise out of the economic base (infrastructure) of society.
Of course, Marx had a lifelong engagement with Hegelian
dialectics, and was more centrally concerned philosophi-
cally with trying to make sense of the social relations
through a theory of praxis, not through a mechanistic
determinism. And it is important to understand how such
dialectical interventions emerging at that time engaged,
and continue to engage, with materialist approaches
unabashed in their determinism. The materialist anthro-
pologist Marvin Harris once remarked that Marx’s mate-
rialism would be palatable if he could just get the
Hegelian monkey off his back (Harris 1979). An extreme
position (and anticipatory of Harris’s reductionist cultural
materialism), it does however underscore a fundamental
difference about what role ideas, beliefs, or immaterial
states have to different kinds of materialists.

Scientific materialism emerged most notably in nine-
teenth-century Germany as a response to idealism and
clerical domination over intellectual life. Ludwig
Feuerbach (1804–1872), a student of Hegel best known
as the inspiration for Marx’s Theses on Feuerbach (1845),
catalyzed a materialist movement that had important con-
sequences for the future relationship between the sciences
and religion. Materialists of this ilk believed that the rapid
advances in science and medicine occurring at this time
constituted evidence of the power of science to answer
questions about the material and immaterial alike as
reflections of biological, chemical, and physical processes.
Such atheism worried many advocates of science and led
to the caricaturing of evolution as an antireligious doc-
trine. The devoutly religious Charles Darwin (1809–
1882) declined Marx’s invitation to dedicate Capital
(1867) to him because he feared further associations with
materialism and social evolutionism.

Scientific materialism did anticipate further problems
in philosophy. Indeed, claims about determinism and
physicalism remain important to the identity thesis in mate-
rialist philosophy, the view that “there are no philosophical
considerations that rule out the possibility that future sci-
entific inquiry will show that every mental state and event is
identical with some material state or event” (Rosenthal 2000,
pp. 8–9; emphasis added). Eliminative materialism, for
example, has been a subject of interest to some of the most
important philosophers of the twentieth century (e.g.,
Richard Rorty, Paul Feyerabend, W. V. O. Quine, Paul
Churchland, and Wilfrid Sellars) who have been con-
cerned with the legitimacy of separating mental states apart
from the physical state in which they take place.

Georgi Plekhanov and Vladimir Lenin are famous for
developing the concept of dialectical materialism. In his
Materialism and Empirio-Criticism ([1909] 1947) Lenin
sought to develop a philosophy of materialism that relied
less on the reductionist claims of nineteenth-century “vul-
gar materialism.” He eschewed the trivializing analogies of
the scientific materialists—such as that thoughts were to
the brain as bile was to the liver—evoked to assert that
nothing other than matter existed, in favor of a material-
ism that saw mental processes as emanating from material
ones. Although also clearly influenced by Feuerbach,
Lenin claimed that the material world (nature) was pri-
mary and the mind and spirit were secondary in a depen-
dent relationship for the development of knowledge.
Some contemporary materialist philosophers remain wary of mind/body dualism generally, in particular of theories that “either deny causal interaction between the mental and the physical, deny causal efficacy to mental states, picture the mental and the physical as being two wholly distinct realms of being, or fail to give integrity to one term of the mind-body relationship” (Peters 1995, p. 8). Notwithstanding philosophical debates as to the efficacy of mental and material realms as categories of analysis, the legacy of materialist philosophy for the social sciences can be said to be twofold. First, materialism abjectly underscores empirical method and observation as essential for an adequate understanding of human societies. And second, it has legitimated the innovation and honing of viable methods for comprehending human action through an emphasis on materiality (and the manipulation thereof) as an entry point of social analysis.

MATERIALITY AND THE METHODOLOGICAL IMPORTANCE OF THINGS

To understand the significance of materialism to contemporary social science, it is necessary to identify the fundamental changes that the academy has undergone in the last two centuries toward the formation of sciences of social processes. In the nineteenth century Auguste Comte (1798–1857) authored a theory of “social physics,” a primitive social science method based on an analogy to the physical sciences that had a profound influence on the development of positivism. The vitality of empirical and positivist theory during this period was aided by the derivation and development of empirical methods that proved successful in their capacity for establishing laws for social processes. The philosopher Ian Hacking (1990) has argued that the honing of techniques for prediction and the establishment of probability in both the physical and social sciences created conditions of possibility for contemporary ways of thinking about the knowability of the world. Among materialist scholars there remains much difference with respect to the degree to which the world is exhaustively knowable. Cultural materialism, for instance, rejects dialectics outright, prioritizing instead positivism, probability, and the primacy of human use of the environment for the understanding of social process. Still, materialist doctrine in the social sciences has become more of an operationalization of a particular positivist method than an outright philosophical account of human activity.

There are a number of methodical approaches to the study of materiality that have become increasingly popular in the social sciences, particularly as all of its disciplines have sought to make sense of social processes that are increasingly informed by global flows of information, communication, and technology. Economics for the most part has always remained unabashedly materialist, methodologically individualist, and positivist as a discipline. Cultural ecological approaches historically have been significant traditions in anthropology and geography. And long-standing subdisciplines such as economic sociology and economic anthropology have gained increased visibility as scholars throughout the social sciences have increasingly queried the meanings and impacts of globalization. Two relevant approaches to the contemporary study of materiality in the social sciences merit particular notice.

Since the mid-1980s there have been numerous studies devoted to the study of a single material object with the aim of understanding the complexities of human global relationships. These commodity biographies have traced the social and economic importance of various globally significant commodities, including tobacco, coal, potatoes, cod, bananas, and salt (see Mantz and Smith 2006, pp. 78–80 for summary). Some of these scholars were influenced by Arjun Appadurai’s groundbreaking anthology *The Social Life of Things* (1986), and accordingly tend to orient themselves to discussions of how consumption of material objects frames political economic relationships. Others, emphasizing the importance of global production systems to the origination of political economic inequalities, originate their work in Sidney Mintz’s *The Sweetness of Power* (1985), or more broadly in the cultural ecology and political economic traditions from which it came. Mintz’s account shows how sugar played an instrumental role in building the economies of industrial Europe around extractive plantation production regimes in the Caribbean. A more recent study has attempted to understand how political economic structural inequalities developed under capitalism are taking on a parallel form in the digital age with the extraction of Congolese coltan, an ore essential to digital technologies such as mobile phones (Mantz and Smith 2006).

At the same time, a growing field of material culture studies has emerged with a specific interest in the consumptive dimensions of human social economic practice (e.g., Miller 2004). Though many of these scholars certainly would not recognize themselves or their approaches as materialist per se, the fact that their entry point remains largely concerned with the human use of material objects indicates their importance to the legacy of materialism in the social sciences. With influences from linguistics and semiotics, and a foundation that engages (at times both sympathetically and critically) with the Frankfurt school, this school of thought has been concerned principally with attempting to unravel the social meaning of objects. This tradition represents a radical break from the traditional domination of studies of the material by materialists. The departure is reflected in a philosophical heritage...
indebted to the early-twentieth-century German sociologist Georg Simmel (1858–1918), as a purported alternative to the materialism of Marxian political economy. A number of the commodity biographies approaches likewise endeavor to move the focus of the study of objects away from their productive sites and instead into the consumptive realms in which they have discernible semiotic and sociological meaning.

There are a number of reasons why the study of material objects has moved away from the materialist philosophy in which it was once firmly ensconced. First, approaches having determinist legacies or “metanarrative” claims have become unpopular among a large number of social scientists, particularly given the influence of postmodernism in the late twentieth and early twenty-first centuries. Second, the end of the cold war has precipitated an increased discomfort with dialectical materialist approaches that were influential to the creation and development of Soviet socialism. At the same time, the scientific materialist approaches of the nineteenth century, as well as the more orthodox approaches of the twentieth century such as cultural materialism, have not been appealing to social scientists uncomfortable with their unwavering dedication to physicalism. And finally, a historic divide between the humanities and sciences—a rift separating what C. P. Snow referred as “two cultures” (1959)—remains unresolved and taxing for the development of a unified and truly interdisciplinary social scientific theory and method. Nonetheless, there remain dedicated approaches to political economy principally influenced by materialist philosophy and method that hold great possibility for unifying various approaches to the study of material objects in the social sciences.

**MATERIALISM, DIALECTICAL**

*Dialectical materialism* was the name given by the doctrinaires and political stalwarts of the Communist Party of the Soviet Union (CPSU) to official Soviet philosophy. Others regarded it more as an ideology, but either way dialectical materialism was a constituent part of the major political innovation of the twentieth-century, official Soviet Marxism. Whether or not dialectical materialism was well formed enough to give adequate or appropriate support to the Soviet experiment is, of course, another question, and a much-debated one. Because CPSU officials and stalwarts were powerful enough to impose their definitions on a captive audience, dialectical materialism—which was commonly given the acronymic form DiaMat—enjoyed a remarkable shelf life during the mid-twentieth century. But, as a concept, its sell-by date is by now long past.

Dialectical was often confused with historical materialism. (In *Dialectical and Historical Materialism*, a book supposedly written by Joseph Stalin during the 1930s, it is unclear whether the author wishes to separate the two or run them together.) Their conflation was and is mistaken: Historical materialism’s register is historiographical—it is a mode of historical and sociopolitical analysis—whereas dialectical materialism, whose register is philosophical and
scientific, throws nature and its laws, along with the supposed “laws” of thought, into the mix. One might say that whereas dialectical encompasses historical materialism, the latter can and did flourish among thinkers to whom dialectical materialism was an embarrassment—Western Marxists and critical theorists prominent among them. The addition of nature and thought, which was first and foremost the contribution of Friedrich Engels (1820–1895), did nothing to make DiaMat philosophically coherent. DiaMat was, rather, a hodgepodge of philosophy and science that confused the pursuit or advance of (mainly scientific) knowledge in the world with the attainment of truth about the world.

At a basic level, DiaMat regarded historical or social evolution as an aspect or facet of natural evolution, and as being subject to the same “laws” as those that govern natural evolution—laws that are said but not shown to be “dialectical” in character. (Engels was as uncomfortable as many other Victorian gentlemen with the aleatory, non-teleological character of Darwin’s principle of natural selection.) When we ask who was the first to run together natural laws, historical laws, and the “laws” of thought, it is Engels, not Marx, who instantly snaps into focus. (Marx, for the record, never even used the term historical materialism, though he did not protest when Engels in a review designated Marx’s method as an instance of “the materialist interpretation of history.”)

While it was Georgi Plekhanov, “the father of Russian Marxism,” who coined the term dialectical materialism, the concept was first authoritatively enacted by V. I. Lenin (1870–1924), who regarded Engels’s and Plekhanov’s legacy as giving intellectual ballast to the copy-theory of perception he advanced in Materialism and Empirio-Criticism (1908). In fact, Lenin’s theory of perception involved a divergence from Engels’s account, since materialism to Engels was not the same as epistemological realism. … [Engels’s] medley of metaphysical materialism and Hegelian dialectics … was conserved by Lenin, but [Lenin’s] own theory of cognition—which was all that really mattered to him—was not strictly speaking dependent on it. Matter as an absolute substance, or constitutive element of the universe, is not required for a doctrine which merely postulates that the mind is able to arrive at universally true conclusions about the external world given to the senses (Lichtheim 1974, pp. 70–71).

(As an aside, the contemporary philosopher Donald Davidson argues that the question whether an accurate representation of reality in thought is possible, let alone desirable—Lenin thought it was both—is undecidable and should be discarded from philosophy altogether.) The compatibility of Lenin with Engels (or Marx, for that matter) was in the event eclipsed by Russian Marxist notables’ need to establish “orthodoxy,” to produce a canon, a continuous, unbroken line of succession stretching from Hegel through Marx through Engels through Plekhanov through Lenin through Stalin (and whoever else was à la page at the time).

Engels of course could have had no foreknowledge of what Soviet stalwarts would do with his doctrine. His sights had been set, not on a nonexistent CPSU, but on German social democracy and, by extension, the Second International (1885–1914). Engels cannot be held directly responsible for the transformation of his speculations into a state dogma imposed on a captive audience. Even so, at a less direct level Engels has much to answer for. He did much to make the sorry Soviet sequence of DiaMat luminaries possible. These swiftly awarded Engels canonical status, and presented him as enjoying a status he had never claimed, as someone coeval and on an equal footing with Marx.

There can be no doubt that Engels’s presentation of his intellectual partnership with Marx, “second fiddle” or no second fiddle, aided and abetted the spurious continuity between Marx and Stalin that DiaMat required. (This continuity was celebrated by cold warriors in the West as well as the East, for it provided the former with an easy—arguably, too easy—target). Such continuity depended throughout on an idea Engels encouraged after Marx’s death in 1883: that in writing about (and conflating) the laws of nature, history, and thought, Engels was faithfully fulfilling his part in an agreed-upon division of labor, according to which Engels produced texts that were interchangeable with Marx’s texts on some subjects and supplementary to, but always compatible with, and true to Marx’s works on others. Without this supposition DiaMat would not and could not have taken the seamless form it took; but there is no evidence that the supposition itself could withstand serious, critical examination.

The disservice done to Marx by the later Engels was a disservice to philosophy at large: It turned Marxism at the official level into the kind of universal weltanschauung or worldview that Marx never intended to provide. Marxism-Leninism constructed around Marx’s writings, to the extent that these were made available (and they were not rushed into print as Engels’s were), a key to unlock every door, a grand theory concerned with the ultimate laws and constituents of the universe. Marx himself had maintained discretion on such cosmic questions. Naturalism and cosmology were domains distant from the critique of political economy that was Marx’s livelihood. Worse still, it was in a sense precisely because Marx had remained reticent on these issues that his self-styled Soviet epigones—to whom such silence seemed unnerving—felt the need to fill in nonexistent gaps and construct a coher-
ent, comprehensive system of materialist metaphysics. Marx's considered reticence, it could be (and was) argued, constituted not a failure of scholarly nerve but a well-judged reluctance to extend his arguments into areas where they could have no meaningful application.

Even though Engels's interpretation of Marxism is in significant respects at variance with what Marx had bequeathed him (and us), Engels took care to advance it in Marx's name. This immeasurably helped DiaMat set the tone for more than a generation of "official" Soviet Marxists. While DiaMat did not pass unquestioned in the West, particularly among Western Marxists and critical theorists, it ruled the roost and attained canonical status in the USSR, its satellites, and China. There was throughout its elaboration an inbuilt, fatal flaw: If nature is conceived materialistically, it does not lend itself to dialectical method, and if, conversely, the dialectic (a category that Hegel had confined within logic, and that was to be of no real use to Marx) is read back into nature, there is no real place or need for materialism. The misapplication of the dialectic into natural processes then either endows the structure of reality with a purposive, teleological striving (which would fly in the face of Darwin, if not of Darwinism), or it stretches the concept of dialectical change to the point of tautology: Anything that happens is said to be a "development" involving qualitative as well as quantitative change (see Lichtheim 1965, p. 254; cf. 247–248).

Paid positions for philosophers who accepted the precepts of DiaMat (or who said they did) came into existence as the fledgling Soviet régime consolidated itself. But, unsurprisingly, "between 1930–1955, philosophical discussions among (Soviet) Marxists were stifled, the publication of books and articles became virtually nonexistent, and the teaching of philosophy in the USSR was greatly reduced" (Loone 1993, p. 158). Engels's third law of dialectics (the negation of the negation) was unceremoniously jettisoned by Stalin, and Engels's first law (the transformation of quantity into quality) was relegated by Chairman Mao to the status of a special instance of Engels's second law (the interpenetration of opposites). These doctrinal modifications could be regarded as refinements, or as signs that DiaMat was beginning to collapse beneath its own weight—even before the political system it was said to uphold imploded at the institutional level. Lichtheim has called DiaMat an "intellectual disaster," and it is not hard to see why. It was also, after all, a kind of politically charged quodlibet for the philosophically tone-deaf.

MATHEMATICAL ECONOMICS

In a narrow sense, mathematical economics, as represented by the Journal of Mathematical Economics or the North-Holland Handbook of Mathematical Economics, is the specialization within advanced economic theory using sophisticated mathematical techniques such as functional analysis and topology. In a wider, more general sense, mathematical economics refers to the application of mathematical methods within economics (other than the application of probability theory and mathematical statistics in economics, which has acquired separate disciplinary status as econometrics). The use of mathematics, together with emphasis on formal economic theory, has become increasingly pervasive in economics since World War II (1939–1945), as general equilibrium analysis, game theory, and operations research became prominent. Training in at least calculus, matrix algebra, and constrained optimization (as well as econometrics) is now indispensable for comprehension of articles in general economics journals, not just journals specializing in economic theory.
There were numerous early attempts to use mathematics to analyze questions in political economy before a receptive audience existed for such works (see Baumol and Goldfeld 1968 for selections from this literature). A few of these early efforts, notably Antoine Augustin Cournot's 1838 analysis of oligopoly, Francis Ysidro Edgeworth's 1881 study of bilateral exchange, and Louis Bachelier's 1900 dissertation on financial speculation and stochastic processes, have been rediscovered and reinterpreted in light of solution concepts developed much later (Cournot oligopoly being viewed by some as a special case of Nash equilibrium, Edgeworth's analysis being related to the game-theoretic concept of the core), but their contemporary readership and influence was slight. Alfred Marshall was educated as a mathematician (Second Wrangler at Cambridge, ranked behind only the physicist Lord Rayleigh) but, unlike his contemporary Edgeworth, he relegated mathematics to a mathematical appendix in his Principles of Economics that, in eight editions from 1890 to 1920, dominated the teaching of economics in English. Although he advocated mathematics as an aid to thought, Marshall distrusted mathematical economics that could not be translated into plain English, and worried about restricting attention only to those considerations that can be quantified. Similarly, as late as 1939, J. R. Hicks restricted formal mathematics to an appendix in his Value and Capital, which brought the continental European tradition of general equilibrium analysis associated with Léon Walras and Vilfredo Pareto in Lausanne to the attention of English-language economists. Along with Roy Harrod, James Meade, and others, Hicks (1937) took a leading role in translating John Maynard Keynes's theory of employment into a small system of simultaneous equations, which Hicks's accompanying diagrams (later modified by Alvin Hansen) turned into the trained intuition of two generations of economists. Keynes himself had made such a translation into a four-equation system in his Cambridge lectures in December 1933 (and the first two published versions of such a model were by David Champernowne and Brian Reddaway, who had both attended that series of lectures), but following Marshall's precedent, Keynes did not include such a formalized model in his General Theory of Employment, Interest, and Money in 1936.

The American economist Irving Fisher had proposed in 1912 the formation of an international society to promote the formal use of mathematics and statistics in economics, but it was only at the end of 1930 that the Econometric Society was founded with Fisher as president (succeeded by the French index-number theorist François Divisia). The Econometric Society's U.S. and European conferences, and its journal Econometrica (founded 1933), provided a forum for mathematical economics and econometrics, as did the closely associated Cowles Commission for Research in Economics (in Colorado from 1933 to 1939, and then in Chicago from 1939 to 1955). The publication of Paul Samuelson's Foundations of Economic Analysis in 1947 (based on his 1941 Harvard dissertation) was a turning point in general acceptance of formal, mathematical economic theory. Samuelson's restatement and extension of neoclassical comparative static and dynamic analysis, introducing a generation of economists to difference and differential equations, emphasized Walrasian general equilibrium analysis, in which all markets are linked through the budget constraints of individual agents. Following from work by John von Neumann and Abraham Wald in Karl Menger's mathematical colloquium in Vienna in the 1930s (see Baumol and Goldfeld 1968, Weintraub 2002), Kenneth Arrow, Gerard Debreu, and Lionel McKenzie provided formal proofs of the existence of general competitive equilibrium in the 1950s, but such works as the 1959 Cowles monograph The Theory of Value by Debreu could be read and understood by very few economists. Gradually, general equilibrium theory, requiring formal mathematics for its statement and application, came to dominate graduate courses in microeconomics (until challenged by game theory since the 1980s), with Marshallian partial equilibrium, susceptible to diagrammatic treatment, prominent only in undergraduate courses.

Military applications encouraged operations research in the United States (and operational research in Britain) during World War II, and postwar research in related fields was supported by the Office of Naval Research, the U.S. Air Force (initially the sole client of the RAND Corporation), and the U.S. Army through the Stanford Research Institute, later SRI (see Mirowski 2002). Discrete optimization (linear and nonlinear programming) was widely used in economics to implement the neoclassical paradigm of agents maximizing an objective function (expected utility) subject to budget and other constraints, as by Robert Dorfman, Paul Samuelson, and Robert Solow in their 1958 RAND study Linear Programming and Economic Analysis. Linear programming and related techniques were entrenched in business schools as operations research, management science, or decision science, and in the Soviet Union and other centrally planned economies as planometrics. Within economics, however, attention shifted from activity analysis (including linear programming) to game theory from the 1970s onward.

Game theory, the formal modeling of conflict and cooperation, emerged as a distinct field of study in applied mathematics and in economics and other social sciences with John von Neumann and Oskar Morgenstern's Theory of Games and Economic Behavior in 1944. This work built on the minimax solution for two-player, zero-sum games, whose existence von Neumann had proved in 1928 (with
a much simpler, non-topological proof provided by Jean Ville in 1938), and with John F. Nash Jr.’s equilibrium concept for n-player, general-sum games. Game theory stressed strategic interaction: the payoffs for each player depend not only on the strategy (a rule for selecting an action in response to a particular information set) chosen by that player, but also on the strategies chosen by all the other players (see “Strategic Games”). Nash equilibrium for a noncooperative game (one in which binding contracts, externally enforced, are not possible) requires that no player can gain from changing his or her strategy under the assumption that no other player changes strategy. Game theory, with its emphasis on strategic interaction among players, contrasts with general competitive equilibrium analysis, which assumes a single agent to be too small to affect market outcomes. In the 1950s and 1960s, game theoretic research, often published in the Journal of Conflict Resolution and some funded by the U.S. Arms Control and Disarmament Agency, focused on the understanding and control of arms races. Game theory is now pervasive in economics from industrial organization to trade policy and the credibility of macroeconomic policy, and is influential in other fields from political science and law to evolutionary biology.

MATHEMATICS IN THE SOCIAL SCIENCES

Methodologically, scientists think that the social sciences differ from the physical sciences in degree but not in kind. The commonality among the sciences is best expressed by Paul A. Samuelson: “All sciences have the common task of describing and summarizing empirical reality.… There are no separate methodological problems that face the social scientist different in kind from those that face any other scientist” (Samuelson 1966, Vol. 3, p. 1756). Another common feature among the sciences is that they use mathematics as a language.

Joseph Schumpeter (1954, p. 955) asserted that in studying quantitative relationships, the knowledge of a handful of simple concepts in calculus—variables, functions, limits, continuity, derivatives, differentials, maxima, minima, system of equations, determinateness, and stability—change one’s attitude to the problem. The applied interest of social scientists is piqued by advances in the frontiers of mathematics and includes, besides calculus, linear programming; information, game, and network theories; and Markov processes, which have industrial, political, social, economic, and military applications (Tucker 1963).

Some have identified stages in the development of mathematics in economics. According to John Hicks, “All through the first period of mathematical economics—the age of Marshall, of Pareto, of Wicksell, even that of Pigou and Keynes—the economist’s main mathematical tool was the differential calculus.… Most economics problems were problems of maxima and minima” (Hicks 1983, pp. 247–248). As in the physical sciences, the approaches to mathematical modeling in the social sciences follow broad methodologies. One simple approach is reductionism, where the laws of one discipline are transplanted to that of another. The physicist Stephen Hawking abides by that rule (Hawking [1997] 2000, p. 169), and so does Samuelson (1966, Vol. 3, p. 1755).

In the social sciences, an abstraction from reality is made in the form of a model that can be expressed in mathematical form. Social scientists tend to divide into two camps in their fundamental belief in the use of mathematical models: Some build models that follow the principle that nature does not make any leaps, and others believe in a dialectical or chaotic process. In either case, a good grasp of the history, statistics, and theory required to function in the social sciences in turn depends on a good understanding of mathematics (Schumpeter 1954, p. 14). In editing mathematical models of the social sciences, James R. Newman (1956) selected classical contributions from the fields of psychology, economics, and sociology. A later book by Kenneth Arrow, Samuel Karlin, and Patrick Suppes (1960) tackles topics in economics, management science, and psychology.

MODELING IN PSYCHOLOGY

An early form of an inner observation model in psychology is Fechner’s Law, after Gustav Theodor Fechner (1801–1887). This law is traced to the work of Ernst
Heinrich Weber (1795–1878), who had conducted several experiments giving subjects weights to hold and asking them to report when they sensed an increase in weight (sensation, $S$). Because sensations cannot be measured, Fechner proposed to observe noticeable differences in sensation. (The expressions that follow use the symbols of Edwin Boring [1956, pp. 1159–1160]). One can measure the stimulus, $R$, as so many pounds of weight, and then record the constant point, $c$, where the stimulus has created a noticeable difference as $dR/R = c$. This relationship takes the form $dS = c(dR/R)$. The implication here is that all changes in stimulus are homogeneous and can be aggregated. One can, therefore, integrate the equation to measure sensation. The integration constant can be approximated by choosing a threshold value of the stimulus, $r$, such that when $R = r$, then $S = 0$. This will yield the expression $S = c \log(R/r)$. By moving to a different base of logarithms and by measuring stimuli in units $r$, Fechner’s Law is expressed in a more compact form as $S = k \log R$. The equation states that as stimulus multiplies in strength, such as in tripling $(3 \times 1)$, the corresponding perception will increase additively, say twice stronger $(1 + 1)$.

By the use of combinatorial mathematics, Kenneth Arrow developed a possibility theorem to show that consistent voting behavior is impossible, even in a democracy. He was preceded by a long line of political theorists who were trying to aggregate individual preferences for a group or society. Attempts by Jean-Charles de Borda (1733–1799) and Marie Jean Antoine Nicolas Caritat (1743–1794) established that the law of transitive reasoning does not hold up when voting preferences are aggregated. A set of voters may choose the candidate $A$ over $B$, and $B$ over $C$, but not $A$ over $C$. Arrow postulated a set of consistent axioms that cannot all be met in the aggregation of social preferences. Besides the transitivity axiom, he required that there be no dictator, that when two choices are ranked their outcome should not depend on the third choice, and finally, that if everyone prefers one outcome over another, the preferred outcome should dominate.

To illustrate Arrow’s model, consider two persons, $X$ and $Y$, who are voting on three candidates, $A$, $B$, and $C$. We can create thirty-six profiles of their ranking, because two persons can rank three outcomes in $6 \times 6 = 36$ ways. Of these thirty-six profiles, $X$ and $Y$ can make only six unanimous rankings, where their first, second, and third rankings can be $\{A, B, C\}$, $\{A, C, B\}$, $\{B, A, C\}$, $\{B, C, A\}$, $\{C, A, B\}$, and $\{C, B, A\}$. In many instances, however, $X$ and $Y$ will not be able to rank the candidates the same. Although they both may rank $A$ first, $X$ might rank $B$ second, and $Y$ may rank $B$ third. The aggregation of these preferences will not, therefore, be unanimous, and this may require a benevolent dictator to pick the final candidate.

**MODELING IN SOCIOLOGY**

As an example of mathematical models from sociology, we take one developed by Arnold Faden (1977, p. 266) as in Alfred Lotka’s predator-prey model, which explains how crime spreads. Loosely speaking, the density of crime at a location has a three-population functional relationship $f(s, c, p)$, where $s$, $c$, $p$, $s$ represent victims, criminals, policemen, and location, respectively. A particular explicit relation of this model can take the form of $f(s, c, p) = vce^p$. One implication of the model is that a crime is possible when a potential victim meets a criminal, assuming no policing, $p = 0$.

From the game perspective, several implications can be modeled. Faden examined cases where victims and criminals follow their individual rationality, where they collude in the absence of police, and where the police and criminals collude, given the distribution of victims. Such modeling represents only the beginning of a complex social problem. The assumption about the size and distribution of the three populations, the functions that relate them, and their motivations can vary. For instance, if we focus on the struggle for existence between two populations, say victims and criminals, the increment of the former will add to the possibility of the latter, yielding a simple system of differential equations such as $(dc/dt)/c = f(c)$ and $(dv/dt)/v = f(v)$. As Samuelson pointed out (1972, p. 474), solutions for these types of equations can lead to perpetual movement in a circle around an equilibrium value. However, the potential for such modeling is on the increase. In the global economy, a country enforcing international trade law can represent the police variable. Consumers, countries, or agents may be the victims, and criminals may be engaged in international piracy of intellectual property rights.

**MODELING IN ECONOMICS**

The classical economists were concerned with how the economy is interconnected. Prices of commodities depend on cost of production (the price of inputs), and output is what is demanded at existing prices. Antoine Augustin Cournot ([1838] 1956, p. 1215) was the first to use calculus in determining both prices and quantities in his model. He formulated quantity demanded as a function of price $D = F(p)$, and foreshadowed the development of the Marshallian elasticity concept by advancing that $\Delta D < 0$ or $\Delta D > 0$. Taking the differential of demand to yield $\Delta D / \Delta p$. Cournot proceeded to analyze maximum problems. 

Cournot has bequeathed a behavioral assumption that makes possible the solution of rivalry problems in modern economics. Each firm assumes that the other firms’ output is fixed. The expected output of the other
firms now enters into the one firm’s own demand curve. If costs are given, the calculus method can be used to find optimal price and output. Variations in demand and cost curves are prominent exemplars in intermediate microeconomics and managerial textbooks.

The founders of the marginal revolution in economics, Léon Walras, Stanley Jevons, and Karl Menger, were influenced by Cournot. They extended Cournot’s model into the theory of the firm, consumer behavior, and general equilibrium analysis. Walras (1954, pp. 103, 110–111) indicated equilibrium where supply and demand curves cross. The markets are related because a change in price in one market affects changes in other markets. A general equilibrium is sought for all markets through the process of *tatonnement*—raising the price in cases of excess demand and lowering it in cases of excess supply until equilibrium is attained.

Paul Samuelson (1966, Vol. 1, p. 544) explained how stability in a Walrasian system can be achieved using differential equations. Solving the equation \( dp/dt = H(qD - q) \) for the term on the left is the rate of change of prices, \( dp \), with respect to changes of time, \( dt \). Given that \( H \) is a proportional constant, \( q \) is quantity, \( S \) is supply, and \( D \) is demand, one can find the time path. Stability occurs when, as time goes to infinity, the solution of the differential equation breaks down, which in economic terms means that the supply curve must cut the demand curve from below. Solving for quantity in terms of price, one can also find the Marshallian stability conditions under which quantity adjusts to clear the market. Malthus’s demographic model used differential equations to show stability. If a population, \( x \), grows at an exponential rate, \( e \), over time, \( t \), then \( dx/dt = ex \). If food supply, \( y \), grows at a constant rate, \( k \), over time, \( t \), then \( dy/dt = k \). Thus, the ratio of \( y/x = (y_0 + kt)/(x_0 e^t) \) will break down as \( t \) approaches infinity, implying misery (Hirsch 1984, p. 14).

Mathematical modeling in economics climaxed with the Arrow-Debreu theorem (1954). In this system, a fixed-point mapping method was used instead of counting equations and unknowns in the Walrasian system. The idea of a fixed point is that, in the process of transforming a rubber sheet, say by stretching it, one point will not move. It will be mapped onto itself. William Baumol (1965, p. 494) explained this process for the case of the demand and supply curves. Starting with demand and supply curves on two separate graphs, let \( Q \) be the quantity supplied, and \( Q \) the quantity demanded. Then, tracing up from the two-quantity axes to the demand and the supply curves, one finds two prices, say a supply price, \( P_s \), and a demand price, \( P_d \). If we can find a function, a map of \( f(P) = P_d \) or \( f(Q) = Q_s \), then we have a fixed point mapping for the equilibrium problem.

The application of the fixed point theorem to the Arrow-Debreu general equilibrium required that convex assumptions be applied on consumers’ and producers’ sets, as well as special ideas of continuity, and the idea of separating planes in Euclidean space. For instance, a commodity has spatiotemporal and physically differentiated characteristics, which can be represented by a point in space. If there are \( L \) amounts of commodities, one can imbibe them in the Euclidian space, \( \mathbb{R}^L \). As Debreu put it, “By focusing attention on changes of dates one obtains … a theory of savings, investment, capital, and interest. Similarly by focusing attention on changes of locations one obtains … a theory of location, transportation, international trade and exchange” (Debreu 1959, p. 32). In his *Theory of Value* (1959) Debreu relied on a lemma of Hukukane Nikaido (1956) to prove equilibrium. The lemma assumes a referee that sets the price, \( P \). Consumers will maximize their utility, \( U(x) \), subject to \( P \times X = P \times A \), where \( A \) is endowment and goods \( X \) is in space \( E = (X_0 \leq X \leq C) \), \( C \) being an arbitrary bundle such that \( C > A \). All acceptable bundles with respect to \( P \) are labeled \( \varphi(P) \), the \( i \)th individual demand function. Its sum is just \( \varphi(P) \). If total demand, \( X \), does not match total available bundles, \( A \), the referee must make an adjustment. The difference is \( X - A \). Its value is \( P \times (X - A) \). The referee’s objective is to pay a person a value \( PX \) that is greater than the endowment value \( PA \). In other words, choose a price, \( Q \), that will maximize the price-manipulating function \( \theta X = (P \times X - A) = \max(Q \times X - A) \) for all \( Q \) in \( S^P \), where \( X \) is total demand lying in \( \Gamma \). We now have the following demand function and a price-adjustment function:

\[
S^P \ni P \rightarrow \varphi(P) \subset \Gamma \text{(Demand function)}
\]

\[
\Gamma \ni X \rightarrow \theta(X) \subset S^P \text{(Price-manipulating function)}.
\]

We want to choose \( (X, P) \) in this demand and price adjustment space, \( \Gamma \times S^P \), such that \( \varphi(P) \times \theta(X) \) is contained in \( \Gamma \times S^P \). This is possible because the mapping is upper semicontinuous. Therefore, the equilibrium price exists.

Upper semicontinuity is easy to show for \( \theta(X) \). Given \( P_s \rightarrow P \in S^P \), \( X_s \rightarrow X \) in \( \Gamma \) and \( P_s \notin \theta(X_s) \), then \( P \notin \theta(X) \). The proof is that, for any \( Q \) price-constellation, \( P_s(X_s - A) \leq Q(X_s - A) \), and, for the whole sequence, as \( n \rightarrow \infty \), we get \( P(X - A) \geq Q(X - A) \). Therefore, the existence of \( P \in \theta(X) \) is demonstrated.

A model developed by Karl Marx has been used as a material balance approach to modeling the economy. Total value is the sum of \( c = \text{constant capital (depreciation)} \), \( v = \text{variable capital (wage bill)} \), and \( s = \text{surplus} \), and the cost price of total capital to produce the commodity is \( c + v \). Assuming turnover rates of 1 for both \( c \) and \( v \), let \( s \) be the total invested capital in one department be 100 units of capital distributed as \( 80c + 20v \) and \( 70c + 30v \) in the other. The average rate of profits is \( s/(c + v) \), and the aver-
age rate of surplus value is \( s/v \). For the first department, \( 80c + 20v, s/v = 20 \), or 100 percent of variable capital, and \( s/(c + v) \) is 20 percent. For the second department, \( 70c + 30v \), the rate of profit becomes 30 percent.

Because of competition, the sum of the profits, 20 + 30 = 50, will have to be distributed evenly across the two departments discussed above, in this case 25 each. Adding this average profit of 25 to the cost price of total capital \((c + v)\) yields prices of $125 for each department. Adding \( s \) to the cost price of total capital yields values of 120 for the first department, and 130 for the second department. The price-value differences are $5 and $–5, respectively, whereas the total values and total prices are the same, each equal to 250. This difference between price and value has been called the “transformation problem” in Marxian economics. Tremendous efforts have been made to solve this problem, and to extend this model to show growth. All in all, the mathematization of the social sciences deepens their ability to probe the human condition.

**Matriarchy**

*Matriarchy* is a complex and controversial term. It is emotionally and politically loaded, and has been seen as suppressed history (Walker 1996b), utopian theory (Perkins Gilman [1915] 1992), deluded fantasy (Marshall 1998), and dangerous degeneration or dysfunction (Frazier 1949; Moynihan 1965). Barbara Walker, citing Wolfgang Lederer’s *Fear of Women*, argues that *Amazon* was a “Greek name for Goddess-worshipping tribes in North Africa, Anatolia, and the Black Sea area” whose women were “warlike” (1996a, p. 24). In Eurasian Scythia women were not only warriors, but also important in politics (Walker 1996a). Similarly, Lewis Henry Morgan’s, whose work was a basis for that of Engel’s, description of the Iroquois certainly points to women holding an important base of power in choosing the leadership and controlling resources, which are contexts of political control of a society (Engels [1884] 1972).

These are relative descriptions, made by those writing the history and/or anthropology of the Other. The fact that there are a variety of versions of mythological and popular renderings of, for example, the Amazons—that they removed a breast for better archery, that they disal-
allowed adult men from living with them, that they practiced infanticide on males—as well as actual evidence of women engaged in both war and politics outside of classical Greek society and ideals, suggests distortional bias. That both the Greeks and the Americans excluded women from soldier and politician roles would make any comparative society in which women were found in these roles on a regular and ordinary basis seem to us like the world turned upside down, and indeed monstrous.

The concept of matriarchy encompasses several component parts that delineate arenas of power and control granted to women. Matriarchy is of course based on motherhood, and how social relations are arranged—especially in terms of the distribution of resources—in relation to how motherhood (and thus fatherhood and other kin relationships) is understood. The two most important components of matriarchy are matrilineal descent or inheritance, and matrilocal living patterns.

If a group determines descent or distribution with a focus on the mother or the mother’s kin network, we refer to this focus as matrilineal. If a group determines where a new couple or family will live with a focus on the mother or the mother’s kin network, we refer to this focus as matrilocal. If these practices are determined with a focus upon the father, they are termed their opposite, patrilineal and patrilocal. Neither matrilineal nor matrilocal practices necessarily add up to matriarchy in the sense of woman-domination of politics, which brings us to the first dilemma in discussing matriarchy, wherein arguments over the meaning of social practices come to the fore. Why is evidence of patrilineal and patrilocal arrangements taken at face value to equal patriarchy (male-domination)? Why does evidence of their opposites (which are abundant) not equal matriarchy? Matriarchy is often discussed as nonexistent, with scholars insisting that there is “no evidence” of it, that it has never existed in any human society (Marshall 1998, p. 402).

In his synopsis of matriarchy, Gordon Marshall points to Friedrich Engels’s reliance upon a notion of evolutionary progress from mother-right to father-right that is now out of favor (1998). Thomas Laquer argues this point from a very different perspective, arguing that patriarchy was embedded in valuing the idea over matter (the body)—historically, fatherhood was considered far more “factual” than motherhood. Thus materiality (bearing the child) does not always make for the logical understanding of connection, where “mother” is assumed as a natural fact and ontologically, whereas fatherhood is often an idea, and not understood as a physical connection (Laquer 1992, pp. 158–164). However, there is more to the Engels argument than Marshall discusses.

As noted above, Engels relied heavily on the anthropology of the Iroquois developed by the American anthropologist Lewis Henry Morgan ([1884] 1972). Morgan noted that Iroquois kinship and economy was organized matrilinearly, and thus that the women held considerable political power, although they were by no means all-powerful. He interpreted this situation as a matriarchy comparable to the more familiar patriarchal male-domination in his own culture, and interpreted matriarchy as a universal stage that preceded patriarchy in the development in human civilization. Engels took this idea of stages of family development and connected it to the Marxist idea of progressive stages of economic development. Certainly, interpreting a contemporaneous social situation—the existence of women’s political power in the Iroquois confederation—as evidence of a worldwide historical stage of evolutionary development in social structure is problematic. However, it is at least equally problematic to ignore what is certainly evidence of a very differently gendered system of distributing power and resources.

Although it is repeatedly stated by scholarly authorities that there are no matriarchal societies in the world today (and many argue there never were), Heide Göttner-Abendroth and the International Academy for Modern Matriarchy Studies and Matriarchal Studies contest this position. Göttner-Abendroth traces the discussion of matriarchal societies to J. J. Bachofen in 1861 (2004; see also Walker 1996). She argues that one of the root words of matriarchy—arche—has a double meaning in Greek: both “beginning” and “domination.” She argues that matriarchy can thus mean “the mothers from the beginning.” But Göttner-Abendroth also asserts that patriarchy is correctly translated as “domination of the fathers.” Her interpretation seems to be a feminist understanding of woman’s power that is always more benevolent than that of man’s. She defines matriarchy as women “hav[ing] the power of disposition over the goods of the clan, especially the power to control the sources of nourishment,” and distinguishes this actual distributive power from “mere” matrilineality or matrilocality (2004). Although in this situation women have this power—and men do not—Göttner-Abendroth and others define matriarchy as egalitarian or consensus-based (see also Walker 1996, and Perkins Gilman’s fictional utopia Herland).

Göttner-Abendroth’s outline of the criteria for a matriarchy is highly formal and detailed. She incorporates a fundamentally different diffusion of the power of women in these societies, one that is based upon consensus in which women are key, because “even the process of taking a political decision is organized along the lines of matriarchal kinship” (2004). She argues further,

In contrast to the frequent ethnological mistakes made about these men, they are not the “chiefs” and do not, in fact, decide…. Therefore, from the political point of view, I call matriarchies egalitar-
Matriarchies or societies of consensus. These political patterns do not allow the accumulation of political power. In exactly this sense, they are free of domination: They have no class of rulers and no class of suppressed people, i.e., they do not know enforcement bodies, which are necessary to establish domination. (2004; emphasis in the original)

Thus, according to a definition that takes into account matri-based kinship strategies, there have indeed been any number of matriarchal societies. According to this definition, there are contemporary matriarchal societies, but they are exceedingly rare, indeed endangered (Jacobs 2003).

Matriarchy and patriarchy are systems of distributing resources and arranging status. In writing about the African American family structure, Robert Staples asks an important question: “does the family determine the economic status of individuals, or does the economy determine the structure of a family?” (1999, p. 19). This emphasis on the relationship between the economy, the family, and the economic success or survival of particular families—and particular individuals in families—is useful. Staples's argument is problematic in that he labels the entire continent of Africa “patriarchal”—without ever defining the term—and never notes from where exactly on that continent the vast majority of African Americans came (West Africa, where there were and are several cultures that can be characterized as “matriarchal” at least in terms of matrilineal descent, and some in the more robust usage of Göttner-Abendroth; see especially Bergstrom 2002). Although critical of both racism and sexism, Staples's structural view of the situation tends to assume that the conventional patriarchal marriage pattern is the one deviants must adhere to, and assumes that pattern to be an inherently stable (read “normal”) one, as did Talcott Parsons, Daniel Patrick Moynihan, and E. Franklin Frazier, among others.

When discussing matriarchy (or more accurately, female-headed families) as a deviation from the norm of patriarchy, Staples does not descend into labeling matriarchy as a dangerous degeneration or a pathology, but he compares the dictatorship of patriarchy to the democracy of gender equality—equality is here valued, but recognized as more of a struggle to maintain (1999, pp. 20–21; see also Frazier 1949 and Dill 1990). Although Moynihan's report “The Negro Family” also was in part an indictment of a racist system that deprived blacks of the normative family relations of their society, its language of pathology tended to normalize what many had already argued—and would continue to argue—was also a pathological social system—patriarchy itself (see Perkins Gilman (1915) 1992, Beauvoir (1949) 1972, and Friedan (1963) 1983).

It is possible to examine the arrangements of sexuality, procreation, management of land and resources, and other essentially political processes as they have existed in every group of people that is an ongoing concern (see Allen 2000). Although we can trace the historical (or even at times the prehistorical) development of particular practices among humans, it is a mistake to view history as inevitable evolution or progression. It is also a mistake to uncritically use one social standard as a measurement device for all others (see Dill (1979) 1990, Dilworth Anderson et al. 1993, and Allen 2000). In the end, both matriarchy and patriarchy may be overly polarizing ideal types that make it difficult for scholarly and everyday analysis of social, cultural, and political arrangements of power. Getting at the nuances of both systemic and individual-level arrangements of power is arguably what is needed here (see Genovese 1972 and Mann 1990 for a brief study that does this admirably).

Matrix, The

The Matrix (1999), a science fiction action movie written and directed by Larry and Andy Wachowski, has been called the masterpiece of "cyberpunk" cinema for the twenty-first century. Cyberpunk, a science fiction subgenre, deals with the adventures of rebellious hackers in the computerized realm of "virtual reality." The subgenre was founded in the early 1980s by a group of American science fiction writers, foremost among them the novelist William Gibson in his novel Neuromancer (1984). Gibson coined the terms “cyberspace” and “the matrix” to refer to virtual reality. The Matrix is a central film dealing with the philosophical issues concerning virtual reality: What is happening to the nature of the human within the new electronic universe humans have created? How can people tell the difference between the real world and a computerized reality? Which is preferable?

The Matrix is the first film of a trilogy about a hacker superhero called Neo who is prophesied to be the savior who will defeat the computers that have enslaved humanity. The film blends the old mythology of the coming of a messiah with the new mythology of virtual reality to create a new kind of religious hero. The first film is the origin story of Neo, who discovers he is living in a computer-constructed world, escapes to the real world, and begins to exercise his extraordinary powers against the agents of the machine. The first third of the film takes the form of a mystery: Both Neo and the audience are at first bewildered by fantastic events. As Neo slowly learns the truth about his world and the nature of his powers, so too does the audience. Gradually the audience realizes that it is 2199 and the surface of the earth has been destroyed in a war with artificially intelligent machines. Deep underground, human beings are bred as a source of energy for the machines and kept lifelong in an embryonic state, dreaming that they are living in an American city in 1999. The dream world of the Matrix is a computer simulation to keep the populace docile.

A few humans remain in Zion, the last human city. Morpheus, the rebel leader, and his crew rescue from the Matrix Thomas Anderson, by day an obscure computer programmer working for a large corporation, by night an outlaw hacker called “Neo.” Morpheus believes Anderson is “the One” who it is foretold can defeat the agents of the machine. But first Neo must be extracted from the Matrix, reborn in the real world, reeducated, and trained.

Today, because of formidable technological obstacles, a program sufficiently complex to simulate real life, including all five senses, well enough to fool people does not exist. The Matrix assumes that in the future these obstacles have been overcome. Many commentators imagine virtual reality as a transcendent space better than ordinary reality, promising a utopian existence. And, in fact, in The Matrix the character Cypher knowingly chooses the Matrix over meager existence in the real world; however, Cypher is a villain who betrays and murders his comrades. Other contemporary critics argue that virtual reality, if it ever exists, would not be transcendent but merely a secondhand existence in a world of shadows, like life in Plato’s cave.

Science fiction and other contemporary cultural concerns about virtual reality project fears and hopes about life inside the machine or life augmented by the machine in the cybernetic age. Humans live now in a new electronic age, not simply the postmodern but "the posthuman." As the boundary lines break down, people fear that
the human may be taken over by the machine, or, at the opposite extreme, hope that the human may be made transcendent by the machine. As critic David Porush (1996) says, virtual reality is “a new mythology” in which the new frontier is not outer space but the “inner space” of the computer and of the human mind and the interface between the two (p. 109).

In Gibson’s novel Neuromancer, cyberspace is a transcendent realm that, for hardcore hackers, is better than drugs or sex. The Matrix taps into this new mythology but inverts Gibson’s notion of cyberspace, creating not a New Jerusalem but a virtual prison, a cyber-hell. Instead, the film openly borrows the ideas of French philosopher Jean Baudrillard, one of the theoreticians of the new order of simulation or virtual reality.

Baudrillard’s central idea is that, in the postmodern world, the real has been almost totally displaced by the simulated, or what he calls the “hyperreal” (1994, p. 1). The real, he believes, has been irretrievably lost, replaced by the electronic and other forms of simulation. Even if people wanted to, they could not distinguish anymore between the simulation and the real. America is in the vanguard of the hyperreal, and the future promises only more and more simulation, he claims.

According to philosopher Slavoj Žižek, The Matrix is not about the future but about the unreality of present-day America in the oppressive, all-enveloping world of virtual capitalism: “The material reality we all experience and see around us is a virtual one, generated and coordinated by a gigantic computer to which we are all attached” (2001, p. 25).

**MATRIX ALGEBRA**

Real numbers can be used to convey one-dimensional information, such as a family’s total expenditure in a month. However, if one wants to record the monthly expenditures of two families (indexed by 1, 2) on three items—food, entertainment, and health (indexed by 1, 2, 3)—then one needs to use a rectangular array of real numbers, or a matrix. A matrix (A) is defined as a rectangular array of numbers, parameters, or variables. The members of the array are referred to as the elements of the matrix and are usually enclosed in brackets, parentheses, or double vertical lines.

\[
A = \begin{bmatrix}
  a_{11} & a_{12} & a_{13} \\
  a_{21} & a_{22} & a_{23}
\end{bmatrix}
\]

The first row of matrix A provides information on the first family’s expenditures on food, entertainment, and health, and the second row gives similar information related to the second family. For instance, \(a_{13}\) is the expenditure of the second family on health, and \(a_{22}\) is the first family’s expenditure on entertainment. Matrix is a concept of linear algebra, and it has wide applications in many fields, including economics, statistics, computer programming, operations research, industrial organization, and engineering.

Like numbers, elementary operations such as addition and multiplication can also be performed on matrices. A typical element in matrix A is written as \(a_{ij}\), which is the element located in row \(i\) and column \(j\) of the matrix. For instance, \(a_{13}\) is the element in the first row and third column, or the first family’s expenditure on health in the first month. Matrix A is also written as \(\{a_{ij}\}_{2 \times 3}\), which simply means that A is a matrix with two rows and three columns whose typical element is \(a_{ij}\). The expenditures of the two families in the second month on food, entertainment, and health can be written as another matrix, \(B = \{b_{ij}\}_{2 \times 3}\). Then, the sum of two months’ expenditures for both families on all three items can be written in the form of a third matrix \(C\), which is the sum of the corresponding elements of \(A\) and \(B\); it is defined as:

\[
C = \{a_{ij} + b_{ij}\}_{2 \times 3} = A + B
\]

Let us now assume that in the third month the two families spend exactly the same amount of money on every item as they spent in the first month. In other words, the matrix of expenditure in the third month is the same as the matrix of expenditure in the first month. Then we can write a matrix D, which will tell us the total expenditure of the two families in three months on each of the three items as:

\[
D = \{2a_{ij} + b_{ij}\}_{2 \times 3} = 2A + B.
\]

2A is called scalar multiplication of a matrix, in which every element of A is multiplied by the scalar 2.
Multiplication of two matrices can be illustrated from input-output models used to illustrate producer theory in economics. Let us suppose that there are two firms, each producing three goods (indexed by 1, 2, 3) with two factors of production (indexed by 1, 2). Let A = \{a_{ij}\}_{2 \times 3} be the matrix of input-output coefficients. Thus, \( a_{ij} \) is the amount of factor \( i \) needed to produce one unit of good \( j \). The first firm wants to produce \( X_1, X_2, X_3 \) and the second firm wants to produce \( Y_1, Y_2, Y_3 \) quantities of the three goods. Let us define a matrix of these outputs as:

\[
Z = \begin{bmatrix}
X_1 & Y_1 \\
X_2 & Y_2 \\
X_3 & Y_3
\end{bmatrix}
\]

Then the matrix multiplication of A and Z can be written as:

\[
AZ = \begin{bmatrix}
a_{11} & a_{12} & a_{13} \\
a_{21} & a_{22} & a_{23}
\end{bmatrix}
\begin{bmatrix}
X_1 & Y_1 \\
X_2 & Y_2 \\
X_3 & Y_3
\end{bmatrix}
= \begin{bmatrix}
a_{11}X_1 + a_{12}X_2 + a_{13}X_3 & a_{11}Y_1 + a_{12}Y_2 + a_{13}Y_3 \\
a_{21}X_1 + a_{22}X_2 + a_{23}X_3 & a_{21}Y_1 + a_{22}Y_2 + a_{23}Y_3
\end{bmatrix}
\]

It may be noticed that A is a 2 \times 3 and Z is a 3 \times 2 matrix. Their product will be a 2 \times 2 matrix. The general rule is that if A is \( m \times n \) and Z is \( n \times q \) then their product will be a matrix of the order of \( m \times q \). The number of columns of A must be equal to the number of rows of Z. If this condition is not satisfied, matrix multiplication is not possible. The meaning of the product matrix \((AZ)\) is very simple. Suppose labor and capital are the two factors of production. The first column of AZ gives the total amounts of factor \( i \) used by the first firm to produce all three goods, and the second column of AZ gives the amounts of all factors used by the second firm to produce these three goods.

The transpose of a matrix \( A^T \) is obtained by interchanging the rows and columns of A. The \( i \)th row of A is the \( j \)th column of \( A^T \). For instance, the transpose of A, written as \( A^T \), is:

\[
A^T = \begin{bmatrix}
a_{11} & a_{21} & a_{31} \\
a_{12} & a_{22} & a_{32} \\
a_{13} & a_{23} & a_{33}
\end{bmatrix}
\]

A square matrix is a matrix with an equal number of rows and columns. The equivalent of the number one is an identity matrix I, which is a square matrix with 1 in its principle diagonal and 0 elsewhere. The following identity matrix is of dimension 3 \times 3:

\[
I = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
\]

Obviously, \( I^T = I \), \( AI = IA = A \), for any matrix A for which these products are defined. A null matrix (written as O) is a matrix whose elements are all zero.

Matrix operations satisfy certain mathematical laws:

1. \( A + (B+C) = (A+B) + C \) (associative law for addition)
2. \( A(BC) = (AB)C \) (associative law for multiplication)
3. \( A + B = B + A \) (commutative law)
4. \( c(A+B) = cA + cB \), where c is a scalar (distributive law for scalar products)
5. \( C(A+B) = CA + CB \), provided the products are defined (distributive law for matrix multiplication)

A crucial application of matrices is that matrix algebra can be used to solve a system of linear simultaneous equations of the form: \( AX = B \). A is a matrix of order \( m \times n \) whose elements are real numbers, X is an \( n \times 1 \) matrix of variables whose values have to be solved, and B is an \( m \times 1 \) matrix of right-hand-side constant terms of \( m \) linear equations. An example of these equations for the case \( m = n = 3 \) follows:

\[
\begin{align*}
x + y + z &= 4 \\
3x + y - z &= 6 \\
x + y - 2z &= 4
\end{align*}
\]

In the above system of equations,

\[
A = \begin{bmatrix}
1 & 1 & 1 \\
3 & 1 & -1
\end{bmatrix}, \quad X = \begin{bmatrix}
x \\
y \\
z
\end{bmatrix}, \quad B = \begin{bmatrix}
4 \\
6
\end{bmatrix}
\]

Something that is equivalent to division for real numbers is called matrix inversion in matrix algebra. Only a square matrix can be inverted. If \( A \) is a square matrix of order \( n \times n \), then its inverse, \( A^{-1} \), is a matrix such that \( AA^{-1} = A^{-1}A = I \). If there is a system of linear simultaneous equations \( AX = B \), where A is \( n \times n \), X is \( n \times 1 \), and B is \( n \times 1 \), then the solution is \( X = A^{-1}B \), provided \( A^{-1} \) exists.

MATURATION

The term maturation comes from maturatio, a Latin word for ripening; thus, many dictionaries describe maturation as the process of “becoming ripe” or “mature,” and being mature as “being ripe.” In the social sciences, when we describe developmental changes as maturational, we are describing the change as having three characteristics: First, maturational change is an intrinsically teleological or end-goal oriented process. Second, maturational change is a systematic process. Finally, the end-goal of maturational change is an adaptive state. Maturity represents this goal-like apex of adaptive functioning, and maturation describes the systematic and time-consuming processes that achieve maturity. Consequently, maturity does not just “happen”; it is a time-consuming and organized growth process.

This definition of maturation is broader than it has been defined historically. For example, the Child Study Movement of the first half of the twentieth century sought to describe child development as a maturational process that is independent of experience and learning. The goal of much of early developmental psychology (e.g., the work of Arnold Gesell and Nancy Bayley) was to chart the course of average and atypical child maturation. This approach, while providing information on the “what and when” of child development, does not explain “why” children develop as they do. Subsequent research has shown that human development is never a purely biological process. For example, there is a documented decrease of about four years in the age of menarche (the onset of menstruation in girls) in Europe and North America over the last century. This is called a secular trend (a trend over a long period of time) and appears to have leveled off in developed nations. However, in the United States there is some evidence that breast development is occurring earlier, although average age at menarche (twelve and one-half years) is not declining. Age at menarche is typically half a year later in most parts of Europe (thirteen years). Age at menarche in nations currently struggling with high rates of disease and malnutrition can be as high as seventeen—where Europe was in the early 1800s. Environmental improvements in nutrition and disease control have the capacity to act on the genetically based timing of female reproductive maturation. Similarly, experiences such as paternal sexual abuse, chemical exposure, obesity, and ongoing stress can speed up pubertal development. On the other hand, severe caloric deprivation (e.g., an eating disorder or famine) can delay the onset of menarche, or even return an adolescent to prepubescent levels of hormonal functioning.

Development is multiply determined; genomes, physical environment, social environment, culture, adaptive history, and even our efforts to retain volitional control by the creation of meanings all contribute to the timing and expression of human development. Genetic code does not have sole control of even physical maturation; instead, the flexible capacity to act on the environment and be acted on by the environment is a core attribute of the human genome. It is increasingly apparent that no aspect of human psychological growth can be understood simply in terms of genetic input. In short, debates that push for allegiance to either nature or nurture no longer fit the data of human development.

Conceiving maturation as a purely biological process shares the same untenable assumption as nature versus nurture debates do; both assume that we can neatly untangle these forces. It is rather like trying to separate conjoined twins who share a brain or heart; each requires something owned by the other. Human development emerges out of dynamic interaction between forces inside and outside our bodies. Additionally, we must remember that there are also less deterministic players in the ring—for example, volition and the cognitive processes of meaning-making. “Purely biological” maturation is an impossibility. As Irving Gottesman and Daniel Hanson put it: “Everything that is genetic is biological, but not all things biological are genetic” (2005). We have probably underestimated the degree to which ever-popular nature-versus-nurture debates have blinded us to the profound and lively interaction of internal and external causes development. At best, these debates are artificial; at worst, they create a peculiar lens through which observations become myopic.

So where does this leave the word maturation? Social scientists still use it to draw attention to biological aspects of development, but few would say they are speaking of purely genetically driven development. Is this word a historical artifact—no longer precise enough for science? If we drop the “purely biological” restriction, does it become a simple synonym of development?

MATURATION VERSUS DEVELOPMENT

Although the term maturation is similar to the term development, from a lifespan perspective it is not synonymous...
with development. Unsystematic changes and declines can still be developmental changes, but they do not have the goal-based character of maturational change. For example, entropic changes toward lesser functionality and greater chaos are developmental changes, but not maturational because they are not systematic and teleological. Lifespan development is quite inclusive; it can include trajectories of gain or decline, systematic or chaotic processes, goal-directed or random ends. If we drop the dysfunctional aspects of maturation’s historic definition (i.e., excluding purely biological assumptions), maturation still includes only growthlike, purposeful, and maximally adaptive changes. For example, throughout a lifespan we find maturational growth in many domains of adaptation, but in the final years of life, nonmaturational developmental change increasingly overshadows maturational development. In contrast, maturational change dominates the pubertal, cognitive, emotional, and social developments of the first two decades of life. Declines of aging also have predictable developmental trajectories, but they less frequently include the systematic, goal-directed, adaptive changes characteristic of maturation. Ultimately death occurs because the organism, at all levels, can no longer maintain the goal-directed and systematic functions that preserve equilibrium.

Caveats about identifying maturational processes
When we designate a segment of development as a maturational change, we must remember that we have done just that—designated. Any dissection of human development into segments imposes onto it our own interests and timelines. In nature, maturation is an integrated whole, but when we describe maturation we would be overwhelmed if we did not focus on particular points of maturity within specific domains. For example, indicators of maturity and their maturational processes will differ depending upon whether one is looking at cognitive maturation, sexual maturation, or emotional maturation; each has its own “maturity” endpoint, yet in reality they are not as distinct as their separate titles would suggest. We may discuss them as separate maturational processes, but from the perspective of the developing organism (e.g., an adolescent), they are a single, dramatically integrated process.

A less obvious relativity is our choice of end goals or mature attributes. For example, the word ripe conjures images of fruit that has reached a stage of maturity we subjectively find delicious. Some say a mango is not ripe until it drops off the tree, because “sweet and juicy” is their conception of maturity. Others like mangos picked a little earlier because they prefer tangy mangos. A mango exporter defines maturity by factoring in shipping time and shelf life. The mango tree, if it could reflect on such things, might wonder at our fuss about its intact fruit; its goal is reproduction—rotting, sprouting, and such things. Reflecting back on human development, if we value maximally efficacious child development, then a mother is reproductively mature when she herself has reached an acceptable level of psychological maturity. If, however, we are only concerned with basic sexual reproduction, then human females generally reach reproductive maturity during the year following menarche. Similarly, if the maturity or “ripeness” being defined is wisdom, our descriptions of what constitutes maturity and the processes needed to achieve maturation may vary considerably across cultures, religions, and historical period.

Maturation—an epigenetic process
Maturation is an epigenetic process because it involves the emergence of new structures and functions through bidirectional relations between all levels of biological and experiential variables. According to Gottlieb: “Individual development is characterized by an increase of complexity of organization (that is, the emergence of new structural and functional properties and competencies) at all levels of analysis (molecular, subcellular, cellular, organismic) as a consequence of horizontal and vertical coactions among the organism’s parts, including organism-environment coactions” (Gottlieb 1991, p. 7).

Genetic determinants of behavior are not fixed or immutable; rather, they have the capacity to respond adaptively, to turn off and on as required by circumstances. More than one gene determines the expression of most attributes, and each gene is embedded in a maturational system that is determined by a multitude of other genetic and environmental inputs. For example, Eric Turkheimer and his colleagues (2003) have found that the genetic heritability of intelligence is influenced by socioeconomic status. In impoverished families, shared environment explained most of the IQ variability among seven-year-old twins and almost none was explained genetically. They found the opposite among affluent families; shared genes accounted for most of the variation in intelligence, while environment accounted for very little. Only bidirectional influence between genetic, experiential, and volitional inputs, or epigenesis, can explain this apparent effect of socioeconomic status on genetic expression.

Maturation—timing and sequence
The fact that maturational timing is highly variable, while process or stage sequence is generally invariant, is a fascinating characteristic of the first two decades of life. For example, the sequence of motor skills developed before an infant is able to walk is quite consistent across individuals,
but the rate at which infants learn to walk is quite variable. Similarly, pubertal maturation follows a predictable sequence of physical changes, but the rate of maturation is highly variable. One adolescent may start and finish pubertal development in a year, while another can take five years to go through the same sequence of change. The timing of female reproductive maturation is more sensitive to environmental and experiential inputs than is male reproductive maturation. This sequential regularity supports the inclusion of systematicity as a characteristic of maturation.

The timing of pubertal maturation has a significant impact on both male and female psychosocial adjustment. In Western cultures, girls who begin pubertal maturation ahead of their peers are more likely to experience depression, premature and exploitive sexual experiences, delinquency, low academic achievement, and school dropout. Because a heavier body type is associated with early pubertal maturation, these girls also experience more body image disturbances and eating disorders. However, early-maturing girls attending same-sex schools do not seem to experience these problems. Boys who mature early experience life differently; they tend to be given more leadership experience, have more success in sports, attract more positive female attention, and have more confidence. The downside of early male pubertal development is greater involvement in delinquent behavior and substance abuse. There is little negative impact of late development on girls. They tend to have the slimmer body type preferred in Western cultures, thus avoiding the body image problems of early developers. Their academic achievement is also significantly higher than that of their early-developing peers. Late-developing boys have more difficulty, with less confidence and more depressive affect, but they do tend to be more creative and achieve more in the end.

CO-OCCURRENCE OF MATURATIONAL PROCESSES
Maturational processes can be correlated or uncorrelated despite occurring within the same period of life. For example, pubertal maturation and the final stages of musculoskeletal and cardiovascular maturation generally co-occur. Other co-occurring maturational processes can be quite independent of each other. For example, the timing of pubertal maturation and adolescent cognitive maturation seem to be unrelated. Adolescent pubertal maturation and its influence on emotion processing (e.g., limbic system) can occur before, during, or after the prefrontal cortex maturation that underlies gains in abstract thinking and self-regulation. Consequently, adolescents whose pubertal maturation precedes their cognitive development are more vulnerable to risk-taking and poor social choices because they have the drives and emotions of puberty without the cognitive maturity to help control their expression.

LIFESPAN PERSPECTIVES ON MATURATION
Developmentalists also use maturation to describe the attainment of skills and capacities achieved later in life. For the adult, both the domains of maturation and the level of maturation reached become individualized. One adult may focus on attaining mature financial skills, while another may focus on attaining mature interpersonal skills or “wisdom.” Experiential opportunities and demands do play a stronger role in adult maturation than they do in childhood, but genetic input is still substantial. Both genes and prior developmental outcomes contribute to cognitive and physical capacity, and choice of environments, experiences, and acquaintances. Another input that may grow in strength across adulthood is volition. The adult capacity for meaning making and thus control over choices creates maturational opportunities that are not available to the young. These opportunities increase individual differences in both areas of competence and the levels of skill (maturity) reached. These individual differences are part of the study of personality and the study of clinical and counseling applications. For all of these areas, maturity refers to maximally adaptive social, emotional, or cognitive functioning, and maturation is the process of achieving it.

MAU MAU
The Mau Mau movement of Kenya was a nationalist armed peasant revolt against the British colonial state, its policies, and its local supporters. The overwhelming majority of the Mau Mau fighters and of their supporters, who formed the “passive wing,” came from the Kikuyu ethnic group in Central Province. There was also represen-
tation in the movement from the Embu, Kamba, and Meru ethnic groups. In addition, available evidence shows that some individual members of the Luo, Luyia, and even Maasai ethnic groups participated in the revolt as well.

Most of the Mau Mau guerrillas were young men and landless peasants. Some of these peasants had lost land to corrupt chiefs and other “landed gentry” in Central Province, while others were victims of land appropriation carried out to enable European settlement. Repatriated African squatters from the white farms in the Rift Valley fueled the ranks of the guerrillas, as did the economically desperate and unemployed Kikuyu in Nairobi and the surrounding urban centers. During the post–World War II period, there was massive African unemployment in the urban areas of Kenya, along with very poor housing (or no housing at all) and high inflation.

Among the Kikuyu, the embrace of a radical political posture was symbolized by taking the oath of unity with and allegiance to the Mau Mau movement. This oath, initially administered at Kiambu in 1950, was supposed to “inject courage into those who were initiated” (Edgerton 1989). It was also supposed to be administered to as many Kikuyu as possible. By July 1952 a new oath, the Batuni oath (“platoon oath”), was introduced. This was a warrior oath and it marked a further radicalization of the Mau Mau, which still remained an underground movement.

When the colonial government, in a panic, declared a state of emergency in October 1952, the Mau Mau were not yet prepared to launch an all-out armed revolt. This started in earnest only after the declaration of a state of emergency, and the arrest and detention of most of the major African political leaders, including Jomo Kenyatta, Fred Kubai, Bildad Kaggia, and Ramogi Achieng’ Oneko.

Throughout the revolt, the Mau Mau guerrillas referred to themselves as the land and freedom army. This description indeed summarized the revolt’s principal causes, which were both economic and political. Scarcity of land, especially in Central Province, remained a major African grievance against the colonial government and white settlers. Hence, the attainment of fertile land, which signified general economic welfare and prosperity for African families, was a major objective of the revolt. To this must be added the demand for vastly expanded opportunities in education, training, housing, and employment. Politically, the Mau Mau guerrillas remained steadfast in their demand for Kenya’s political independence from Britain. The Mau Mau movement’s political objectives and even its ideology did not differ from the aims and objectives of the mainstream political independence party, the Kenya African Union (KAU); both sought political freedom (Uhuru) and the restoration of African dignity. From 1944, when it was formed, until 1953, when it was banned, KAU was the preeminent African political organization in Kenya. Its formation represented the “first attempt at territorial nationalism,” and also the most prominent “legitimate political outlet” for Africans (Maloba 1993, p. 51). Still, KAU’s political agitation did not lead to any remarkable victories. By 1947 none of its leaders, including Kenyatta, expected Kenya to achieve its political freedom during their lifetime.

One of the distinguishing features of the Mau Mau is that it remains perhaps the only major nationalist revolutionary movement to have been led almost entirely by peasants, many of them illiterate. The movement had no external sources of political or material support. Even the British government arrived at this conclusion, having determined that the Soviet Embassy in Addis Ababa, Ethiopia, had not provided any help whatsoever to the revolt or even established any verifiable contacts. The movement also lacked any propaganda machinery to spread its message beyond Central Province. Together with the British government in London, the colonial government in Nairobi took advantage of this weakness, and launched a harsh and effective propaganda campaign against the Mau Mau and Kenyan nationalism. The revolt was portrayed as irrational, and as a reversion to primitive savagery by Africans traumatized by the stress of modern (Western) civilization. The British government firmly maintained the position that the revolt was not caused by economic conditions, but rather an organized criminal enterprise. In this propaganda offensive, a lot of emphasis was placed on the oaths taken by the supporters of the revolt; almost routinely, many of these oaths were described as “bestial.” It is this image as a senseless, savage, murderous enterprise that would haunt the Mau Mau for many years to come. In the West, major newspapers and magazines carried stories on the Mau Mau that reinforced British propaganda. Robert Ruark’s Something of Value (1955), a novel read widely in Britain and the United States, also echoed official propaganda by contrasting “white heroism” with “black savagery.”

For four years from October 1952 to 1956, the Mau Mau guerrillas operated from the forests of Mount Kenya and the Aberdares. Although they were outgunned throughout the duration of the revolt, these guerrillas fought with singular courage and determination against the combined forces of the colonial government’s army, British troops, and the Home Guards (paramilitary units of local Kikuyu/Embu/Meru people supporting the colonial government’s military and political objectives against the Mau Mau fighters and their objectives). One of the most celebrated leaders of the Mau Mau was Dedan Kimathi, who was based in the Aberdares, and who sought, in 1953 and 1954, to establish some unity among the various guerrilla units operating in the forests. These efforts did not succeed, and as a result the Mau Mau never had an overall leader or commander.
In response to the revolt, the British government undertook a major rehabilitation campaign in Central Province in order to “remake Kenya” by defeating radicalism and reinforcing the power of the conservative Kikuyu “landed gentry” and the Home Guards. Members of these groups would emerge triumphant in the post-emergency period. The rehabilitation campaign was carried out in the detention camps and even in the Kikuyu reserve. Its objective was to get the detained and arrested Kikuyu to renounce the Mau Mau and its radicalism. Christian religious indoctrination, sanctioned by the colonial government, played a major role in the rehabilitation process.

Although defeated militarily, the Mau Mau revolt was clearly instrumental in forcing the British government to undertake immediate political reforms. These reforms included the reinstatement of African political parties in 1955, and then the promulgation of several constitutional reforms that eventually led to the attainment of political independence on December 12, 1963.

The legacy of the Mau Mau revolt in Kenya remains a very complex and controversial subject. The controversy revolves around the following issues: What role did the revolt play in the decolonization of Kenya? Did Mau Mau bring Uhuru? Who benefited from Uhuru, the Home Guards and their descendants or the actual Mau Mau supporters and fighters? Was the Mau Mau a Kikuyu affair or a national movement? And lastly, how should this very complex movement be remembered in Kenya?

MAXIMIN PRINCIPLE

The maximin principle is a principle for making choices when one is not sure of the outcome that will result from one’s choice. The principle says to evaluate each option in terms of the worst possible outcome that could result from choosing that option, and to pick the option that offers the best worst outcome (the maximum minimum or maximin). Rational choice theory generally divides situations in which agents do not know for sure the outcome of their choices into three types: risk, uncertainty, and games. In situations of risk, the probabilities of various outcomes resulting from particular choices are known. In situations of uncertainty, those probabilities are not known, and in some cases the possible outcomes are also unknown. Games are strategic interactions, where the outcome that results from each player’s choice is determined not merely by external—possibly random—factors, but by the play of other rational agents.

Maximin is both risk and uncertainty averse, because it minimizes the degree of risk or uncertainty faced by the agent. Many rational choice theorists argue that risk aversity is irrational, as it involves a kind of double counting, valuing the mere avoidance of risk over and above its effect on the expected value of the possible outcomes. Subjects in psychological tests display a fair range of attitudes toward risk, from positively valuing it to extreme risk adversity. Some rational choice theorists argue that aversion to uncertainty is more rational, and experimental results confirm that aversion to uncertainty is more widespread. Finally, in the case of games where the gains of one’s opponents are one’s own losses (so-called zero-sum games),...
Maximin strategies are more clearly rational. If player one’s opponent, player two, is rational, and player two’s maximizing behavior will have the effect of giving player one the minimal result that can arrive from the options that player one faces, then it is rational for player one to try to maximize over those minimums. Furthermore, if such games have what is called a pure-strategy equilibrium, it will result from all players adopting a maximin strategy.

The importance and notoriety of the maximin principle outside of rational choice theory is due in large part to its connection with John Rawls’s *A Theory of Justice* (1971). Something resembling a maximin principle appears at two crucial moments in Rawls’s argument for the conception of justice he calls justice as fairness. First, at the heart of justice as fairness are two principles of justice, part of the second of which is the so-called difference principle. The difference principle states that social and economic inequalities are to be arranged to give the greatest benefit to the least advantaged members of society. Because the difference principle requires maximizing the share of goods that go to those with the smallest share, it is often described as a maximin principle of justice. Rawls rejected that name, however, because of its tendency to be confused with the maximin principle of choice.

Second, Rawls’s argument for the two principles, from what he calls the original position, is often thought to involve an invocation of the maximin principle. In the original position, artificial rational agents must make a unanimous choice about principles of justice for a society, and do so without any particular knowledge about the people they represent or their society. Rawls argues that in such a situation, purely rational agents would choose his principles of justice over utilitarian principles. Many have read that argument as resting on the claim that it would be rational to use the maximin principle for choice in the original position. Such critics as John Harsanyi then argue that because the maximin principle is not a rational principle for choice under risk, Rawls’s argument fails. Defenders of Rawls’s theory (including Rawls himself) have offered three sorts of replies: (1) Risk aversion in the original position is rational because of the stakes and finality of the choice; (2) the choice in the original position is really one under uncertainty, not risk, and aversion to uncertainty is a much weaker and thus more defensible assumption to make than aversion to risk; (3) the original position is best thought of as a game, whose players are looking for an equilibrium, and this justifies their adoption of the maximin principle. In his *Justice as Fairness: A Restatement* (2001), Rawls further clarifies the role of the maximin principle in his argument, arguing in addition that its role is limited to supporting the adoption of his first principle, which guarantees adequate liberties to all, rather than the second principle, which includes the difference principle.

**MAXIMIZATION**

In modern economics agents are assumed to maximize, so naturally the structure of the maximization assumption has had a significant impact on the structure of modern economics. On one hand, the widespread use of maximization has given economics an intellectual unity not seen in most of the social sciences; on the other hand, the reliance on maximization threatens to halt empirical and theoretical progress in economics.

Nobel Prize winner Paul Samuelson should be credited with making maximization the foundation of modern economics. In his influential *Foundations of Economic Analysis* (1947), Samuelson demonstrates that consumer and firm behavior could be usefully modeled as solutions to what are now known, in mathematics, as classical programming problems.

In general, the classical programming problem takes the following mathematical form:

\[
\text{Max } \sum_{i=1}^{n} F(x_1, x_2, \ldots, x_n) \text{ subject to:}
\]

\[
g_1(x_1, x_2, \ldots, x_n) = b_1
\]

\[
g_2(x_1, x_2, \ldots, x_n) = b_2
\]

\[...
\]

\[
g_m(x_1, x_2, \ldots, x_n) = b_m
\]

The \(n\) variables \(x_1, x_2, \ldots, x_n\) are the instruments. The function \(F()\) is the objective function, and the \(m\) functions \(g_1(), g_2(), \ldots, g_m()\) are the constraint functions. The constants \(b_1, b_2, \ldots, b_m\) are the constraint constants. Interpret the instruments as a representation of the choices available to the agent. Interpret the objective function as a representation of the agent’s desires with respect to the choices. Finally, interpret the constraint functions and constants as a representation of the limits the environment imposes upon the agent’s choices. Under these inter-
pretations, the classical programming problem becomes a model of constrained maximization by an agent. If certain mathematical assumptions are met, a solution to the classical programming problem exists (Intriligator 1971). The method of LaGrange multipliers can be used to find a solution. Once a solution is deduced, compare its characteristics against the agent’s observable behavior. If there is a match, the agent’s behavior has been explained. If not, change the mathematical structure and repeat the process.

It is important to recognize that although the classical programming version of constrained maximization was new to most economists at the time of Samuelson’s Foundations, the idea of constrained maximization was familiar. Constrained maximization is merely a sophisticated version of what the philosopher Daniel Dennett (1987) calls the “intentional stance.” The intentional stance is a strategy for prediction and explanation. The first step in taking an intentional stance toward something—call it Z—is to attribute beliefs, desires, and rationality to Z. Since Z is assumed to be rational, the attributed beliefs and desires ought to make sense in the context of Z’s circumstances. One can then predict (or explain) Z’s behavior by determining what is rational given Z’s attributed beliefs and desires. Since there is always leeway in the attribution of beliefs and desires, if a prediction turns out wrong, or an explanation does not impress, the intentional stance need not be questioned for we can always revise the beliefs and desire we attribute to Z. The intentional stance is practically irrefutable.

As Dennett notes, there is nothing particularly profound about the intentional stance. It is “folk psychology,” “familiar to us since childhood and used effortlessly by us all every day” (Dennett 1987, p. 7). Yet when Samuelson merged the intentional stance with classical programming, he elevated this folk psychology to science. Think of Thomas Kuhn’s (1962) definition of normal science as the relatively routine puzzle-solving activity of trained professionals. All can use the intentional stance effortlessly; few can do classical programming effortlessly, even with training.

Economic theorists at the research frontier quickly mastered the classical programming version of constrained maximization and began rapidly to transform the discipline. Mechanisms were created to select and reward mathematical skill. In one generation—the late 1940s to the late 1970s—the leading periodicals in economics, the leading economics departments in America, the minimal mathematical proficiency levels of American graduate students in economics, and the standards defining scholarly success in economics all changed. The mathematical goals of rigor, generality, and simplicity became widely shared imperatives in economics. The Nobel Prize winner Gerard Debreu uses the term: “the matematization of economic theory” (Debreu 1991) to refer to this evolution.

To illustrate the nature of this evolution, consider the discovery of nonlinear programming by Harold Kuhn and Albert Tucker (1951). The nonlinear programming problem is similar to the classical programming problem described above; the only differences are that the constraint functions are inequalities (≤) and the instruments \( x_i \) (i = 1, 2, ..., n) are nonnegative (≥ 0). However, surface similarities mask deep differences; mathematically, nonlinear programming is better than classical programming. Nonlinear programming imposes fewer restrictions than classical programming, and it is based on a less complex mathematical foundation (convexity) than classical programming (differentiability). Given the new emphasis on rigor, generality, and simplicity in economics, on the battlefield of economic theory, nonlinear programming wiped out classical programming. Yet empirically speaking there is no difference between the two types of mathematical programming. Not surprisingly, modeling with nonlinear programming did not lead to new empirical generalizations.

Once maximization opened the gate to matematization, constrained maximization became even more entrenched as the preferred method of doing economics. If you like rigor, generality, and simplicity then you like mathematical programming. So after years of selecting and rewarding mathematical skill, by the late 1970s the field of economics had as much consensus in the National Science Foundation’s peer review system as the fields of chemical dynamics and solid-state physics (Cole, Cole, and Simon 1981).

Of course the consensus is incomplete. One of the earliest and most profound critics of constrained maximization is the Nobel Prize winner Herbert Simon. In 1955 Simon proposed satisficing as an alternative explanation of economic behavior, and throughout his career he urged economists to take a more empirical approach to their science. For more than four decades Simon carefully observed agents making choices, created theories, and devised experiments and computer simulations to test his theories. His work helped create two brand-new disciplines: artificial intelligence and cognitive science. Further, the primarily empirical research produced by two cognitive scientists inspired by Simon—Daniel Kahneman and Amos Tversky—received one of the 2002 Nobel Prizes in economics.

The work of Simon, Kahneman, and Tversky is very different from the economics produced after matematization. To explain the difference, let us return to Dennett. In developing his notion of the intentional stance, Dennett has often referred to a contrasting strategy for prediction and explanation; he calls this strategy the
design stance (Dennett 1987, pp. 16–17). Simon, Kahneman, and Tversky can be interpreted as applying the design stance toward human beings, and the first step in taking this sort of design stance is to figure out “how the machinery which Nature has provided us works” (Dennett 1987, p. 33). Figuring out the human machinery and implementing the intentional stance on a system of mathematical objects are two tasks divergent in empirical content. In which direction will economics go? Will it remain on the deeply mathematical track of constrained maximization, or will it move toward Simon and become more empirical?

Pierre-Andre Chiappori and Steven Levitt (2003) categorized every microeconomics paper in three prestigious economics journals between the years of 1999 and 2001. Consider three of their categories: (1) price theory, which “refers to basic economic principles and techniques used by economists in the 1950s and before” (p. 152); (2) applications of price theory, which “refer to the testing of simple economic ideas … in domains outside the traditional purview of the field” (p. 152); and (3) behavioral economics, which gives us a rough indicator of research in the spirit of Simon, Kahneman, and Tversky. The table includes the percentages of the paper types that Chiappori and Levitt placed in these three categories.

The pattern displayed in the table invites the question: If a high proportion of the most talented current economists are exploring economic ideas that were well known a half century ago, and few seem inspired by the current revolutions in cognitive science and artificial intelligence, will economics continue to achieve empirical and theoretical progress?

### MAXIMUM LIKELIHOOD REGRESSION

Maximum likelihood is a methodology used to estimate the parameters of an econometric or statistical model. It was first proposed by Ronald Aylmer Fisher (1890–1962) and is now considered the workhorse of modern econometrics, not only because of its flexibility but also due to the availability of computer power, which has permitted the resolution of complicated numerical problems associated with this technique. Maximum likelihood estimation seeks to determine the parameters of a statistical process that have the highest probability of generating the observed sample of data.

Consider the following regression model: $Y_i = \beta_0 + \beta_1 X_{i1} + \ldots + \beta_k X_{ik} + \varepsilon_i$ for $i = 1, 2, \ldots, n$. In the simplest case, one can assume that the error term $\varepsilon_i$ is an independent and identically distributed (iid) normal random variable with variance $\sigma^2$; that is, $\varepsilon_i \sim N(0, \sigma^2)$. It will be shown below that the assumption of a particular density function for $\varepsilon_i$ is paramount to write the likelihood function. Under the assumption of normality, the probability density function of the error term is written as

$$f(\varepsilon_i) = \frac{1}{\sqrt{2\pi \sigma^2}} \exp \left( -\frac{\varepsilon_i^2}{2\sigma^2} \right).$$

Since $\varepsilon_i = Y_i - \beta_0 - \beta_1 X_{i1} - \ldots - \beta_k X_{ik}$, the assumption of normality of the error term is equivalent to the assumption of normality for the conditional probability density function of $Y$ given $X$: $f(Y \mid \beta_0, \beta_1, \ldots, \beta_k, \sigma^2) = N(\beta_0 + \beta_1 X_{i1} + \ldots + \beta_k X_{ik}, \sigma^2)$—that is,
Maximum Likelihood Regression

\[ f(Y_{i} | X_{1i}, X_{2i}, \ldots, X_{ki}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left( -\frac{(Y_{i} - \beta_0 - \beta_1 X_{1i} - \ldots - \beta_k X_{ki})^2}{2\sigma^2} \right). \]

The objective is to estimate the parameter vector \( \theta \equiv (\beta_0, \beta_1, \beta_2, \ldots, \beta_k, \sigma^2)' \). For a sample of size \( n \), and because of the iid assumption, the joint probability density function of \( \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n \) is then the product of the marginal densities: \( f(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n; \theta) = f(\varepsilon_1; \theta) f(\varepsilon_2; \theta) \ldots f(\varepsilon_n; \theta) \). The likelihood function \( L(\theta; \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n) \) is based on the joint probability density function of \( \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n \) where \( \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n \) is taken as fixed data and the parameter vector \( \theta \) is the argument of the function: \( f(\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n; \theta) \). Note that \( \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n \) is a function of the data \( (Y, X) \) through the regression model; that is to say, \( \varepsilon_i = Y_i - \beta_0 - \beta_1 X_{1i} - \beta_2 X_{2i} - \ldots - \beta_k X_{ki} \).

Though the aforementioned regression model deals with a cross-sectional data set, the maximum likelihood principle also applies to time-series data and panel data. For instance, a time-series regression such as \( Y_t = \beta_0 + \beta_1 X_{1t} + \varepsilon_t \) for \( t = 1, 2, \ldots, T \), with iid \( \varepsilon_t \to N(0, \sigma^2) \), implies that the conditional density function of \( Y_t \) given \( Y_{t-1} \) is also normal, \( f(Y_t | Y_{t-1}) \to N(\beta Y_{t-1}, \sigma^2) \), that is,

\[ f(Y_t | Y_{t-1}) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left( -\frac{(Y_t - \phi Y_{t-1})^2}{2\sigma^2} \right). \]

As before, the object of interest is to estimate \( \theta \equiv (\phi, \sigma^2)' \) and the likelihood function for a sample of size \( T \) is \( L(\theta; Y_1, \ldots, Y_T) = f(Y_1; \theta) f(Y_2; \theta) \ldots f(Y_T; \theta) \). This function requires the knowledge of the marginal density of the first observation \( f(Y_1; \theta) \). When the sample size is very large, the contribution of the first observation is almost negligible for any practical purposes. Conditioning on the first observation \( Y_1 \) is known we define the conditional likelihood function as \( L(\theta; Y_{1}, Y_{2}, Y_{3}, \ldots, Y_T) = f(Y_2 | Y_1; \theta) f(Y_3 | Y_2; \theta) \ldots f(Y_T | Y_{T-1}; \theta) \).

Mathematically, it is more convenient to work with the logarithm of the likelihood function. The log-likelihood function is defined as:

\[ \lambda(\theta) = \log L(\theta; \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n) = \sum_{i=1}^{n} \log f(\varepsilon_i; \theta) \]

The maximum likelihood estimator (MLE) of \( \theta \) is the value of \( \theta \) that maximizes the likelihood of observing the sample \( (Y_{t}, X_{1, t}, X_{2, t}, \ldots, X_{k, t}) \) \( t = 1 \ldots n \). In estimating a regression model using maximum likelihood, the question is which value of \( \theta \equiv (\beta_0, \beta_1, \beta_2, \ldots, \beta_k, \sigma^2)' \), out of all the possible values, makes the possibility of occurrence of the observed data the largest. Since the log transformation is monotonic, the value of \( \theta \) that maximizes the likelihood function is the same as the one that maximizes the log-likelihood function. The statistical inference problem is reduced to a mathematical problem, which under the assumption of normality, looks like:

\[ \max_{\theta} \lambda(\theta) = \max_{\theta} \sum_{i=1}^{n} \log f(\varepsilon_i; \theta) \]

\[ = \max_{\theta} \left[ -\frac{n}{2} \log(2\pi\sigma^2) - \frac{1}{2} \sum_{i=1}^{n} \frac{(Y_t - \beta_0 - \beta_1 X_{1i} - \ldots - \beta_k X_{ki})^2}{\sigma^2} \right]. \]

Equating the first-order conditions (the score vector of first-order partial derivatives) to zero results in a system of \( k + 2 \) equations with \( k + 2 \) unknowns. The solution to this system is the maximum likelihood estimator. The solution is the maximum of the function if the Hessian (the matrix of second-order partial derivatives) is negative semi-definite.

For a linear regression model, the MLE is very easy to compute. First, we compute the solution for the system of equations corresponding to the parameter vector \( (\beta_0, \beta_1, \ldots, \beta_k)' \). This system is linear, and its solution is identical to the ordinary least squares (OLS) estimator that is, \( \hat{\beta}_{\text{OLS}} = \hat{\beta}_0 = (X'X)^{-1}X'Y \). Second, the maximum likelihood estimator of the variance is straightforward to compute once the MLE \( \hat{\beta}_i \)'s are obtained. The MLE \( \sigma^2 \) corresponds to the sample variance of the residuals \( \hat{\sigma}_{\text{ML}}^2 = \frac{1}{n} \sum (\varepsilon_i^2) / n \), which is a biased estimator of the population variance. The \( \hat{\beta}_{\text{ML}} \) is identical to the \( \hat{\beta}_{\text{OLS}} \) when the likelihood function is constructed under the assumption of normality.

For a nonlinear regression model, the system of equations is usually nonlinear, and to obtain the MLE solution numerical optimization methods are needed. In addition, there is the possibility of heteroscedasticity. This is the case when the variance of the error term is not constant but it depends on a set of variables, for instance, \( \sigma^2(X, \gamma) \). In this instance, there is an additional set of parameters \( \gamma \) to estimate. The system of equations will be nonlinear and the solution will again be obtained by numerical optimization. In nonlinear models, the system of equations may have several solutions, for the likelihood function may exhibit a complicated profile with several local maxima. In this case, the researcher needs to make sure that the global maximum has been achieved by either plotting the profile of the likelihood function (when possible), or by using different initial values to start the iterative procedures within the optimization routine.
The significance of the maximum likelihood estimator derives from its optimal asymptotic properties. In large samples and under correct model specification, the MLE $\hat{\theta}_{\text{ML}}$ is in most cases consistent, asymptotically efficient, and asymptotically normal. Among these properties, maximum efficiency (estimators with the smallest variance) is the most significant property of the ML estimator. Maximum efficiency is a very desirable property because it allows the construction of more powerful tests and smaller confidence intervals than those based in less efficient estimators.

Within the maximum likelihood framework and after obtaining the ML estimators, we can also perform hypothesis testing by comparing the value of the estimates with other fixed values. The likelihood ratio test assesses the likelihood that the data may have been generated by a different set of parameter values (those under the null hypothesis). The test compares the value of the likelihood function under the null hypothesis with that under the alternative. The test is computed as two times the difference of the log-likelihood functions and it is asymptotically distributed as a chi-square with as many degrees of freedom as the number of parameters under the null.

The maximum likelihood estimator is also known as a full information estimator because the estimation is based on the most comprehensive characterization of a random variable, which is the specification of its probability density function. In practice, it is not known what density function should be assumed, and a potential shortcoming of the maximum likelihood estimator is that one could write a likelihood function under a false probability density function. The consequences of this are severe, for the asymptotic properties will not hold anymore. However, one can still apply quasi-maximum likelihood estimation (QMLE). The QML estimator requires that the conditional mean and conditional variance are correctly specified. It assumes that the error is normally distributed, though this may be a false assumption. The quasi-maximum likelihood estimator is still consistent, though the maximum efficiency property is lost. The efficiency loss depends on how far the normal density is from the true density. In practice, estimation is done within the quasi-maximum likelihood framework, because a full knowledge of the density is rare. Other estimators can recover some of the efficiency loss but, these belong to the family of nonparametric and semiparametric estimators.

**MCCARTHYISM**

The term *McCarthyism* refers to an accusatory campaign based on unfair allegations, fear tactics, innuendo, and sensationalized threats of guilt by association. *McCarthyism* was coined by political cartoonist Herbert Block (1909–2001) in a March 29, 1950, *Washington Post* cartoon lampooning the anticommunist campaigns of Senator Joseph Raymond McCarthy (1908–1957), a Republican from Wisconsin, in the 1950s. McCarthy was elected to the U.S. Senate in 1946 and rose to national prominence after newspapers reported on a speech he made in Wheeling, West Virginia, on February 9, 1950, in which he claimed to have a list of 205 State Department employees who were members of the Communist Party. McCarthy’s list later shrank to eighty-one, then fifty-seven, but McCarthy’s facts mattered little to the press or his public.

When McCarthy became the chair of the Permanent Investigations Subcommittee of the Senate Committee on Governmental Operations in 1952, he used this position to investigate alleged Communists. In 1953 the committee identified “subversive” books held at American embassy libraries around the world. Books by authors such as Owen Lattimore (1900–1989), Lillian Hellman (1905–1984), Langston Hughes (1902–1967), and Dorothy Parker (1893–1967) were removed from libraries because of allegations that the authors were either fellow travelers or Communists. In late 1953 McCarthy investigated the U.S. Army after an army dentist was promoted despite his refusal to answer questions on a federal loyalty oath. McCarthy’s inquiries soon led to investigations of a number of army officers.

Journalist Edward R. Murrow (1908–1965) broadcast a critical analysis of Senator McCarthy’s tactics in March 1954 on the CBS program *See It Now*. This broadcast brought increased public scrutiny of McCarthy. In April 1954 the Senate began the Army-McCarthy hearings, investigating McCarthy’s claims that the army was promoting Communists in its ranks. The hearings were nationally televised, allowing the nation to witness McCarthy’s bullying and fabricating of evidence. On June 9, 1954, McCarthy’s rapid descent began after a televised hearing.
showed army special council Joseph Welch (1890–1960) rebuffing McCarthy for his scurrilous tactics. Welch berated McCarthy before the cameras for his reckless bullying, rhetorically asking, “Have you no sense of decency, sir, at long last? Have you left no sense of decency?”

The Senate censured McCarthy on December 2, 1954, by a vote of seventy-six to twenty-two. McCarthy remained in the Senate, but his power was greatly diminished. He died of sclerosis of the liver in 1957. For all his bluster and claims to hold secret evidence of American Communism, McCarthy never identified a single Communist spy.

The social impacts of McCarthyism were significant. Some victims of McCarthyism lost jobs, were blacklisted, were alienated from friends and associates, or committed suicide. McCarthyism generated a climate of self-censorship. President Dwight D. Eisenhower (1890–1969), members of Congress, intellectuals, celebrities, and everyday citizens muted criticisms of McCarthy out of fear of being called procommunist (Schrecker 1998).

The Federal Bureau of Investigation (FBI) had a symbiotic relationship with Senator McCarthy. FBI director J. Edgar Hoover (1895–1972) had conducted free-ranging investigations of the American political Left since the 1930s, and the FBI secretly and illegally provided Senator McCarthy with records and names of individuals.

Functionally, McCarthyism deadened what might have been a critical activist edge in American social science as those who fought for racial or economic justice or who studied social stratification were routinely interrogated by the House Un-American Activities Committee (HUAC) or subjected to FBI surveillance and harassment (Harris 1980; Keen 2004; Price 2004). Proponents of McCarthyism were not simply interested in exposing and destroying Communists. McCarthyism's outcomes were much broader and included attacking labor union leaders, as well as discrediting a wide range of social activists working for gender, racial, and economic equality.

Loyalty hearings made examples out of public figures associated with progressive causes. In 1952 playwright Arthur Miller (1915–2005) began work on his play The Crucible, set during the 1692 Salem witch trials. The Crucible, which opened in New York in 1953, used the past to examine the 1950s climate of fear, accusations by informers, guilt by association, and the right of communities to bring moral judgments.

McCarthyism's mechanisms of social control extend beyond the mid-twentieth century's “Red Scare.” The use of fear, guilt by association, vague accusations, and claims that dissent is dangerously unpatriotic to generate silence and compliance is a recurrent instrument of social control employed in various societies before and since the 1950s (Garfinkel 1956).

McFadden, Daniel L.
1937–
Daniel L. McFadden, a physics undergraduate who switched to behavioral science (economics) in graduate school, won the Nobel Prize in economics (Bank of Sweden Prize in Honor of Alfred Nobel) in 2000. McFadden's best-known economic contribution and the one that led to his winning the Nobel Prize was the theoretical development and econometric evaluation of discrete choices involving multiple outcomes.

Discrete choice outcomes had been a vexing problem in economic analysis. Typically, economic decisions have been framed as trade-offs between goods in which quantities of goods could be traded over relatively continuous ranges. Discrete choices, by contrast, are “lumpy”: One choice precludes the possibility of choosing another option. For example, the same consumer cannot choose simultaneously to drive and to take the train to work on the same morning.

Modeling discrete outcomes requires a theoretical framework for discrete choice and empirical innovations that allow researchers to investigate the factors that influence the outcomes of choices. McFadden provided the theoretical linkage by adopting the basic precepts of a random utility model in which the agent is assumed to maximize utility but the researcher cannot observe the full set of factors that lead to the choice; the agent also cannot do this because of cognitive and information limitations.

The limited decision-making capacity of the agent, along with the limited information researchers have about the factors that lead to a decision, results in a set of determinants that are unobservable in the modeling process.
This insight implies that the errors associated with decision-making are especially important in estimating discrete choice models. The idea of unobserved preference heterogeneity serves as the theoretical foundation of McFadden’s well-known multinomial logit model.

In a multinomial logit model McFadden assumes that there is a latent (unobserved) variable that represents the indirect utility (satisfaction) associated with each discrete choice. One set of independent variables measures the attributes of the choice. A second set of variables measures the individual attributes affecting tastes. A fundamental assumption of McFadden’s discrete choice models is that current economic conditions affect the feasibility of a choice through the budget constraint but not the preferences of the individual. Thus, prestige goods, or “snob” goods, are not modeled adequately using McFadden’s theoretical foundation.

Although the theoretical foundations for the multinomial logit model are complex, the empirical estimation of that model has become increasingly simple. Most of the empirical methods developed by McFadden, such as multinomial logit, conditional logit, and other nested models, have been standardized enough that they are easy to estimate. However, the interpretation of the results is less straightforward. Estimates are interpreted relative to the “base” category (often the most common choice), and every other outcome has its own set of parameter estimates. One consequence of this is that when there are many choice outcomes, interpretation of the results is difficult. In particular, neither the sign nor the magnitude of the parameter estimates indicates the direction of the influence of the independent variable on the outcome. Typically, marginal effects must be calculated for each variable of interest.

A second difficulty with the multinomial logit model is that the observed attributes of the choices must provide a systematic mapping onto the agent’s preferences. If arbitrary attributes are used to categorize choices, the multinomial logit model will provide incorrect estimates of the effects of independent variables. This difficulty is known as the independence of irrelevant alternatives (IIA) problem. The issue of IIA points to the importance of understanding, classifying, and defining the choice set.

**McLUHAN, MARSHALL**

**1911–1980**

In 1964, when Canadian educator and social theorist Marshall McLuhan’s *Understanding Media* appeared, the terms medium and media were generally understood in the sense of intermediary or intermediate. The media were not recognized as a subject of study; reviewers and teachers cautioned that the word was obscure and needed definition. McLuhan’s radical observation was that it is the medium (not the program content) that shapes and controls the scale and form of human association and action:

“The message of any medium or technology is the change of scale or pace or pattern that it introduces into human affairs. The railway did not introduce movement or transportation or wheel or road into human society, but it accelerated and enlarged the scale of previous human functions, creating totally new kinds of cities and new kinds of work and leisure. This happened whether the railway functioned in a tropical or northern environment, and is quite independent of the freight or content of the railway medium. (McLuhan 1964, p. 8)

This is essentially a sociological outlook, though it has not been adopted by that field. Yet *Understanding Media* did serve to found the field of media study in North America and ultimately throughout the world.

Among its groundbreaking insights were that some media involve the user deeply (“cool media”), while others (“hot media”) do not: The involvement takes place on the sensory level, below consciousness. For example, the movie viewer must supply all of the movement that occurs on the screen between frames while the screen is black. The television viewer or computer user supplies most of the mosaic image from moment to moment and nearly all of the color. These effects, which occur independently of the content or uses, shape the sensory preferences of the users and supply new perceptual biases that affect how they construe their cultures and societies.

McLuhan was the first to study advertising seriously: In his first book, *The Mechanical Bride* (1951), he called advertising the “Folklore of Industrial Man.” This work applies then-new critical techniques (practical criticism, developed in England) for the first time to ads and other facets of North American popular culture. McLuhan followed it with *Culture Is Our Business* (1970), a companion study of advertising after television.

*The Gutenberg Galaxy* (1962) delved into the manner in which print and the press reshaped culture and sensibility in the centuries that followed their introduction and showed how to study the social-environmental actions of new media. *Take Today: The Executive as Dropout* (1972)
examined the effects of electric media on management practice and business culture.

*Laws of Media: The New Science* (1988), written with his son Eric, sought to place McLuhan’s style of environmental media study on a scientific basis for the first time. In it, the authors proposed that four invariable laws govern the action of all media—and also of all human artifacts. Briefly, every human artifact extends or amplifies some process or faculty; obsolesces some established pattern; reinvigorates or retrieves some older, previously obsolesced form that now returns in a new shape or guise; and reverses its characteristics when pushed to its limit. The four laws exhibit an inner relation to each other as A is to B as C is to D.

During his life, McLuhan was a controversial figure, not least because his techniques of media study departed so radically from the established methods, which focused on content analysis and research into the desires and motivations of audiences. McLuhan, in contrast, approached media study from the angle of perception and changes in sensibility occasioned by media as forms and as extensions of the users’ senses. Although McLuhan’s work remains controversial, his techniques work as well now as they did in his time, to the chagrin of those who have tried to apply them superficially, without first understanding how perception is modified by media.

**MEAD, GEORGE HERBERT**

**1863–1931**

George Herbert Mead was one of the core founders of pragmatism, a distinctively American philosophy. Mead was a professor of philosophy at the University of Chicago (1894–1931), but he had a powerful influence on both philosophy and sociology. He is also recognized as one of the originators of symbolic interactionism, an important discipline within sociology. In this regard, he is famous for showing the relationships between mind, self, and society: Our minds and selves are gifts we receive from society, though we can augment and alter mind, self, and society in countless ways (Mead 1934).

Mead and the other pragmatists argued that the scientific method is the most powerful tool humans have ever discovered for analyzing knowledge, and that they applied empirical methods to all knowledge—including science, philosophy, government, religion, ideologies, and everyday life. Mead argued that we should treat all ideas as hypotheses that are open to analysis in terms of the consequences associated with using them. It is true that many religious people and ideologues are not used to thinking that their favorite ideas are hypotheses that can be tested by examining how well they work, but pragmatists treat all knowledge as tentative and open to investigation.

Any ideas that work well when we act on them are tentatively supported as useful and valid. On the other hand, ideas that lead to failures are identified as problematic. This is most obvious in the realm of science. A medical procedure that prolongs life without problematic reactions is seen as valuable, but a procedure with adverse side effects alerts researchers to either abandon the technique or rework it until the problems are overcome. Pragmatists treat all ideas in a similar manner. For example, many American professors defended Marxism and communism during the mid-1900s, and pragmatists are not surprised that some abandoned these theories after the collapse of the Soviet Union and the Communist nations of Eastern Europe. Even if an idea was once popular, pragmatists emphasize that a series of failures often leads people to abandon or revise prior views: Countless positive
claims about an idea are not as powerful as a succession of failings.

No theory can ever be proven so conclusively as to be completely above question and possible future revision. Pragmatists argue that tentative and flexible truths are in fact more useful than the dogmas or static “truths” that ideologues defend. Our physical, biological, and social worlds are in constant change; hence, it is wise to approach all knowledge as likely to need modification as we attempt to track our ever changing and evolving world.

Pragmatism has had major influences on philosophy, sociology, science, and many other domains of thought. Mead’s version of pragmatism is highly nuanced because, as the youngest of the pragmatists, he benefited from the best ideas of his predecessors.

MEAD, MARGARET

1901–1978

Margaret Mead was an American anthropologist whose career as a social scientist and public intellectuals spanned the greater part of the twentieth century. She was an indefatigable fieldworker whose ethnographic research focused primarily on the study of small-scale societies in the South Pacific and Bali, but she was also well known for her insights about and prescriptions for American society. Mead received her PhD in anthropology in 1925 from Columbia University, where she worked with Dr. Franz Boas and Dr. Ruth Benedict, two anthropologists well known for their work on race and cultural relativism, or the idea that no culture or racial group is inherently superior to another and that any cultural practice can be understood within the context of the larger social structure and cultural whole of which it is a part. Along with Benedict, Mead was a major contributor to the development of the school of culture and personality, a subfield of cultural anthropology that sought to understand the role that culture played in shaping the personality of individual members of a particular society. Influenced by neo-Freudian theory of the 1930s and 1940s, Mead sought to apply psychoanalytic concepts about the individual—especially the development of a child into an adult—to the study of socialization in non-Western societies. Although aspects of culture and personality theory have been disparaged, many of the topics that Mead first investigated formed the basis for today’s subfield of psychological anthropology.

After Mead returned from her first trip to Samoa in 1926, she became curator of anthropology at the American Museum of Natural History. She remained at the museum for the rest of her lengthy career. Mead’s fame arose from her ability to write books that captured the general public’s interest with their engaging prose and provocative and timely choice of topics. Beginning with her first book—Coming of Age in Samoa—published in 1928, Mead became a best-selling author and an increasingly well-known expert on topics of primitive cultures, adolescence, gender and sexuality, education, child development, and culture change. While Coming of Age in Samoa established Mead’s reputation as an anthropologist who studied sexuality, especially the sexual behavior of adolescent girls, subsequent books focused on education in so-called primitive cultures (Growing Up in New Guinea), gender roles and male-female relations (Sex and Temperament in Three Primitive Societies and Male and Female), acculturation (The Changing Culture of an Indian Tribe), the relationship between culture and the development of adult personality (Balinese Character), national character (And Keep Your Powder Dry), Mead’s first anthropological book about American culture), New Lives for Old (about cultural transformation and the impact of Western development on traditional societies), and Culture and Commitment (Mead’s analysis of the generation gap).

During World War II (1939–1945) Mead worked for the U.S. government, contributing studies on American food habits, morale building, and the interpretation of British and American culture for British civilians and American soldiers in the United Kingdom. After the war Mead shifted her focus to the application of anthropological methods to the study of American society, the Soviet Union, and the effects of development faced by newly independent nations. As a result of her increasing media presence on television, in popular magazines, and the radio, by the time she died Mead was famous worldwide and eulogized as “grandmother to the world.”

In 1983, five years after Mead’s death, Australian anthropologist Derek Freeman published a detailed critique of Mead’s Samoan research, ultimately claiming that Mead’s informants had duped her and that her conclusions about the relative freedom toward premarital sex she had claimed characterized Samoan society were false. Moreover, Freeman concluded that if Mead’s Samoan
findings were false, so too was the larger claim she had made about the relative importance of nurturance versus biologically innate characteristics of human behavior. Although Mead was not able to respond to Freeman’s critique herself, many anthropologists who had worked in Samoa, or who were proponents of the importance of cultural factors in shaping human behavior, came to her defense. They did so despite their acknowledgment of some factual errors in her Samoan research, which they claimed were of minor significance and the result of her youth and the infancy of anthropology as a social science. (For a detailed discussion of the critique of Freeman’s argument and defense of Mead’s work, see Caton [1990], Orans [1996], and Lapsley [1999]). In November 1983 the American Anthropological Association censured Freeman, citing inconsistencies and errors in his critique of Mead’s Samoan research. However, although the media coverage of the Mead-Freeman controversy damaged Mead’s public image, in 2001 the American Anthropological Association and the media honored Mead during her centennial year. This asserted her prominence as a public figure whose major contribution had been to apply anthropological methods and insights gleaned from the study of remote small-scale societies into the analysis of contemporary American society and the solution of problems that vexed complex modern societies in general.

MEADE, JAMES
1907–1995

During his long career as an economist, James Edward Meade made major contributions to many fields, including national income accounting, economic growth, public finance, and welfare economics, as well as the two most important, for the discipline and for the world economy, macroeconomics and international economics (trade and finance). For his contribution to international trade and finance he was awarded the 1977 Nobel Memorial Prize in Economics jointly with Swedish economist Bertil Ohlin (1899–1979).

As an undergraduate at Oriel College, Oxford, Meade switched from the study of classics to economics, motivated by the serious unemployment problem in Britain in the 1920s. Upon graduation with first-class honors in 1930, he was appointed to a fellowship in economics at Hertford College, which first allowed him a postgraduate year at Trinity College, Cambridge. He swiftly became a member of the Cambridge “circus” of young economists—including Richard Kahn (1905–1989), Austin Robinson (1897–1993), Joan Robinson
Meade, James

(1903–1983), and Piero Sraffa (1898–1983)—whose criticism of John Maynard Keynes's (1883–1946) A Treatise on Money (1930) set Keynes on the path to The General Theory of Employment, Interest, and Money (1936). Meade returned to Oxford already a “Keynesian” in the modern (i.e., post-1936) sense, and published the first Keynesian economics textbook, An Introduction to Economic Analysis and Policy, in 1936. Throughout his career his main concern was with the contribution economic analysis can make to practical economic policy. One of several young Oxford economists advising the Labour Party in the 1930s, he was a “liberal socialist” who believed in using the market mechanism for egalitarian ends. He was also a convinced believer in international political and economic cooperation.

In 1937 Meade joined the Financial Section of the League of Nations and wrote two of its World Economic Surveys before World War II (1939–1945), when he returned to England to work for the British government. In government, he and Richard Stone (1913–1991) prepared the first modern double-entry social accounts for any country, published as An Analysis of the Sources of War Finance and an Estimate of the National Income and Expenditure in 1938 and 1940, accompanying the first “Keynesian” budget of April 1941. He then concerned himself with planning postwar macroeconomic policy. It was Meade who wrote, in March 1943, the first draft of what became the wartime coalition government’s Employment Policy (1944). He was also a founding father of the GATT (General Agreement on Tariffs and Trade). To complement Keynes’s “clearing union” plan for the postwar international currency system, Meade proposed an “international commercial union” to restore multilateral trade and remove trade restrictions after the war. The two plans formed the basis of the British contributions to wartime Anglo-American discussions on the postwar international economic order. Meade’s ideas bore fruit in the Anglo-American Proposals for Consideration by an International Conference on Trade and Employment of December 1945, and he served on the preparatory commission for the conference that drew up the charter for an International Trade Organization. Although the charter was not ratified, its main principles were incorporated in the GATT, negotiated in Geneva in 1947.

Meade returned to academic life in 1947 as Cassel Professor of Commerce with special reference to international trade at the London School of Economics. There, as a direct result of his wartime work on economic policy, he was to make his most lasting contributions to economic theory when he began to write on international economic policy. He began by constructing a general-equilibrium comparative static model for an economy open to trade and capital flows, synthesizing Keynesian and classical theory and extending it in order to analyze the effects of different policy instruments and other variables on internal and external balance. The result, The Theory of International Economic Policy, Volume 1: The Balance of Payments (1951a), and its supplement containing the mathematical model (1951b), was the first systematic exploration of the relationship between domestic and international equilibrium. The model has become “part of the baggage of every economist” (Corden and Atkinson 1979, p. 529), the most important single influence behind the development of open-economy macroeconomics in the next four decades.

The equally pathbreaking second volume, Trade and Welfare (1955a, 1955b), made three major and lasting contributions to economics: a fundamental reformulation of the theory of economic welfare to make it both operational and more widely applicable; the use of this new theory to analyze controls on factor movements as well as controls of trade; and the extension of the analysis from two-country models to a many-country world, including its application to the theory of customs unions (1955c). He originally drafted much of the book on the basis of the “new welfare economics” of the late 1930s, but he rewrote it to utilize the work (1951) of his former wartime colleague, Marcus Fleming (1911–1976). “It was a brilliant feat of imagination … to realize … [Fleming's method] was capable of large-scale generalization into a powerful tool for welfare analysis of practical policy problems, and an act of great intellectual honesty and courage for him to scrap his existing draft and rework the whole problem on the new approach” (Johnson 1978, p. 73).

From 1968 Meade was based in Cambridge, first as professor of political economy in succession to Dennis Robertson (1890–1963), A. C. Pigou (1877–1959), and Alfred Marshall (1842–1924). He worked on the theory of economic growth (1961a) and income distribution for ten years before returning to macroeconomics to lead a major research project on Stagflation (Meade 1982; Vines et al. 1983). He concentrated on the reform of wage-fixing arrangements, in order to solve the problem of the dual function of the price mechanism: The prices of goods and factors of production that promote the most efficient use of resources may well produce an unacceptably unequal distribution of income. His consistent concern for both efficiency and equality is spelled out most clearly in Efficiency, Equality, and the Ownership of Property (1964), which he himself regarded as his best book. It was also a feature of two “Meade Reports,” The Economic and Social Structure of Mauritius (1961b) and The Structure and Reform of Direct Taxation (1978), and his final book Full Employment Regained: An Agathotopian Dream (1995). An inveterate explorer of improvements in economic arrangements, he should be remembered for his practical contributions as well as for his theoretical achievements.

**MEAN**

**SEE** Descriptive Statistics.

**MEAN, THE**

The mean is widely used throughout the social sciences and is the arithmetic average of a set of scores. It is simply the sum of all the scores of interest divided by the number of scores. In casual conversation this calculation is referred to as “getting the average.” The capital letter $M$ is commonly used in journal articles to represent the mean. The formula for the mean is quite simple: $M = \frac{\sum X}{N}$, where $M$ is the mean, $\sum X$ is the sum of all the scores of interest, and $N$ is the number of the scores.

In general, what is sought is a single value that represents the location of the set of scores on some scale. The mean describes the central tendency of a distribution of scores. In other words, it describes where the scores tend to cluster together or the arithmetic middle point of the scores. This measure of central tendency is sometimes referred to as the index of location.

The mode and the median are also used to describe central tendency; they lack, however, the mathematical properties of the mean. These other measures are most useful when the distribution of scores is multimodal or skewed.

A simple example will illustrate the mean. Assume one has five scores: 6, 5, 4, 3, and 2. The sum of these scores is 20. The mean is 20/5, which equals 4. In this case the median is also 4 (it is the score that divides all the
scores in half). This is usually the case when the distribution of scores is symmetrical. This example can also illustrate an advantage of the mean over the median. The mean is sensitive to all the scores in the distribution, while the median is not. Look at what happens if the score of 6 is changed to a score of 16. The new sum of the scores is now 30, and the mean is 30/5, which is 6. But the median is still 4. The mean reflects the value of every score in the distribution. Of course, in the social sciences one often encounters distributions that are essentially normal, in which case all three measures of central tendency (mode, median, and mean) will be the same.

For many variables in the social sciences the mean is the standard descriptor of central tendency. For example, the mean may be used to describe a person’s average grade in a course of study or a person’s average weight over a given period. The mean is useful in describing groups as well. Demographic data are often presented as means (e.g., mean age, height, weight, number of children, or siblings). The average performance of a class of students, a school, a school district, a state, or the whole country may be reported on some measure of academic achievement. Even countries may be compared on average academic skills.

In research or evaluation the characteristics of a population of interest often need to be described. Populations, however, are typically very large (sometimes infinitely so) and impossible to measure completely. The truth about a population may only be inferred. For this reason a sample is collected from the population, with the intent of generalizing the results to the whole population. Once the sample scores have been obtained, the data need to be described in such a way as to communicate the essential characteristics and also allow inferences about the population—briefly but informatively.

The sample mean is an unbiased estimator of the population mean. It determines a center point of the set of scores that includes the value of every score in the set. Because the mean includes all the scores, it is the point of balance or center of gravity of the distribution.

Much research is concerned with trying to determine how different or how similar people or groups may be. The mean is used to do this. The measurement of how far individuals are from their group mean is taken, and also the measurement of how far group means are from the mean of all the samples. The resulting scores are called deviation scores, and are obtained by subtracting the mean from the individual score. These deviation scores can be used to calculate another average called the variance (because the sum of the deviation scores is always zero, they must be squared before being added together and dividing by the number). The square root of the variance is called the standard deviation. This average tells one about the amount of variability in a set of scores or among a set of means.

This property of the mean is critical because much research is concerned with examining how much sample means deviate from some point or from each other. If the means deviate from each other by a large enough amount, they are said to be “significantly different.” This is the basis for significance testing between groups. These significance tests are commonly found in published research, although there is debate about which approach to use and how results should be reported.

The mean is arguably the most widely used measure of central tendency. It requires interval or ratio level of measurement, works best with distributions that are unimodal and roughly symmetrical, and is the basis for much statistical decision-making.

**MEANING**

In the social sciences, the concept of meaning has been understood theoretically in three different ways, which can be called the mirroring, constructivist, and production perspectives.

The mirroring perspective derives from the work of Max Weber (1864–1920), who called attention to the subjective interpretations that people create to describe or explain their social experience. Whether or not these meanings are conveyed to others, they are social to the extent that they are broadly characteristic of those who share a similar position within the structure of social relationships. For example, according to a study of television audiences in Israel, the meanings viewers ascribed to the
American television series *Dallas* had much more to do with ethnicity than with whatever meanings might have been intended by the show’s scriptwriters and directors. Arabs saw the show as a moral drama exemplifying how American immorality inexorably led to chaos in interpersonal relationships, while Jews who recently immigrated from Russia saw it as a social drama portraying the evils of the capitalist system (Liebes and Katz 1990). Similarly, in the United States and United Kingdom, men and women have been repeatedly found to view corporate leadership roles differently. For most men, effective leadership means setting up a forceful and consistently applied system of rewards and punishments. For most women, it means showing others how to transform one’s individual goals into group goals so that teams can work more effectively and harmoniously (Alimo-Metcalfe 1995). In the mirroring perspective, the social meanings that people are found to have about the social world are seen to stem from their differing experience of a social structure in which prestige, wealth, and power are unequally distributed. Although shared social meanings can foster a sense of shared identity, when viewed through the lens of the mirroring perspective, they are essentially epiphenomenal and close to irrelevant for explanatory purposes. For example, studies of corporate leadership styles have largely failed to demonstrate that these differing meanings are related to the style female leaders actually choose.

The constructivist perspective, in contrast, emphasizes how people employ agency in order to create and deploy social meanings within fields of social relations that are contentious, fluid, and imperfectly defined: a world of becoming rather than being. This perspective derives from a variety of 1960s theoretical innovations, including symbolic interactionism, phenomenology, sociolinguistics, anthropological linguistics, ethnomethodology, structuralism, social movement theory, pragmatics, and social constructivism. The constructivist perspective turns the mirroring perspective on its head: Social structure is seen as the consequence of the constant and contentious efforts people make to create meanings and, by means of communicative behaviors, to frame social situations in terms of those meanings. In its most radical forms, constructivists deny that what Émile Durkheim (1858–1917) would call “social facts”—objectively measurable patterns of social behavior that are external to individual motivations—have any a priori existence whatsoever. For example, medicine has struggled unsuccessfully for decades to define a “self-neglect syndrome” in objective, medical terms. If a self-neglect syndrome can be said to exist in an objective sense, it is only because, within the field of medical relations, some patients have emphasized “self-neglect” behaviors in order to frame the situation in light of their understanding of it; alternatively, a medical organization has identified certain patient behaviors as “self-neglect” in order to alter the patient’s position and rights within a medical organization.

The production perspective, the most recent of the three, derives from the work of British sociologist Anthony Giddens (1993) and, more recently, the flourishing subfield of cultural sociology. It seeks to strike a balance between the mirroring and constructivist perspectives by emphasizing the dialectic between, on the one hand, social forces that really are larger than the individual (such as institutionalized discrimination), and, on the other hand, the attempts by individuals and groups to try to frame situations to their advantage. In order to do so, they draw on the stock of meanings at hand, but they also create new ones or repackage the old ones in new ways. From the production perspective, the interpretation of *Dallas* offered by Arab citizens of Israel is part of a broader meaning-formation strategy that is being pursued by Sunni Arab communities throughout the Middle East: It involves a rejection of the secularism and perceived immorality of Western societies in favor of a radically reformulated, fundamentalist version of Islam known as Wahhabism. In contrast to constructivist approaches, which almost invariably emphasize interpersonal interaction as the medium in which meanings are defined, the production perspective is equally attuned to the institutions, technologies, and media that meaning-producers appropriate as they attempt to frame the meaning of situations. For example, the rise of Islamic moral and religious fundamentalism in Sunni Arab communities is clearly related to Saudi Arabia’s lavishly funded and influential system of religious schools and to the rise of Arabic media, including satellite television stations, that are independent of Western control and censorship.

MEANS, RUSSELL
1939–

Russell Means, an Oglala Sioux, is one of the most lionized and controversial American Indians of the twentieth century. Means rose to national prominence as an American Indian Movement (AIM) spokesperson and negotiator during the 1973 Wounded Knee occupation on the Pine Ridge reservation in South Dakota. The occupation lasted seventy-one days, ending with two occupiers dead and two federal officials seriously injured. Means faced several charges stemming from the Wounded Knee occupation, but they were eventually dismissed.

Means was not a founding member of AIM, an American Indian civil rights organization started in Minneapolis in 1968, but he did establish a local chapter in Cleveland and became the group’s first national director in 1970. His other political activities include a 1970 lawsuit against the Cleveland Indians baseball team over the Chief Wahoo mascot; the 1972 takeover of the Bureau of Indian Affairs (BIA) office in Washington D.C.; and protests against Columbus Day observances and parades in 1992.

His relationship with AIM became strained over the years, and he resigned in 1986. By 1993, AIM factions had officially split, with Means developing the International Confederation of Autonomous Chapters of the American Indian Movement; and fellow American Indian activists Vernon Bellecourt (b. 1931) and Clyde Bellecourt (b. 1939) heading up the American Indian Movement–Grand Governing Council.

Means admitted to criminal activity in his 1995 autobiography, Where White Men Fear to Tread; his legal troubles include several arrests and trials, a felony conviction for the 1974 Sioux Falls courthouse riot, and a 1975 murder charge. Although Means served one year in prison for the riot conviction, he was pardoned in 2002 by South Dakota governor Bill Janklow; he was acquitted on the murder charge.

In 1997 he was arrested on the Navajo reservation for assaulting his father-in-law. Scheduled to be tried in the Navajo Nation court system, Means argued that he was not subject to its jurisdiction. In 2005 the U.S. Court of Appeals for the Ninth Circuit ruled the Navajo Nation does have misdemeanor criminal jurisdiction over non-member American Indians, including Means. Critics contend that Means’s effort to thwart Navajo jurisdiction was an attack on tribal sovereignty to further his own interests, whereas Means argues that he was attempting to uphold Navajo treaty rights with respect to jurisdiction over lawbreakers. The U.S. Supreme Court declined to hear the case.

Means has also made several attempts to work within the political system. He made three unsuccessful bids for the presidency of the Oglala Sioux Nation in 1974, 1984, and 2002. In 1984, Means was Hustler magazine publisher Larry Flynt’s running mate in the latter’s unsuccessful attempt to secure the Republican nomination for president of the United States. In 1988 Means lost his bid to be the Libertarian Party’s presidential nominee. He entered the New Mexico gubernatorial race as an independent in 2002 but ultimately withdrew.

Means is also an actor, securing roles in The Last of the Mohicans (1992), Pocahontas (1995), and Thomas and the Magic Railroad (2000). Means prefers the term American Indian over Native American because he believes “anyone born in the Western hemisphere is a Native American” (Means 1998).

MEASUREMENT

Measurement is the evaluation or estimation of degree, extent, dimension, or capacity in relation to certain standards (i.e., units of measurement). As one of the most important inventions in human history, the process of measuring involves every aspect of our lives, such as time, mass, length, and space. The Greeks first developed the “foot” as their fundamental unit of length during the fourth millennium BCE. The ancient peoples of Mesopotamia, Egypt, and the Indus Valley seem to have all created systems of weight around the same period. Zero, the crucial number in the history of measurement, was first regarded as a true number by Aristotle.
Measurement

The ancient Egyptians first developed a systematic method of measuring objects, which they used in the construction of pyramids. During the long period during which their civilization thrived in northeastern Africa, they also cultivated the earliest thoughts on earth measurement: geometry. Euclid of Alexandria (c. 330–c. 275 BCE), a Greek mathematician who lived in Egypt and who is regarded as the “father of geometry,” provided the proofs of geometric rules that Egyptians had devised in building their monuments. His most famous work, Elements, covers the basic definitions, postulates, propositions, and proofs of mathematical and geometric theorems. Euclid’s Elements has proven instrumental in the development of modern science and measurement.

Another great mathematician who contributed to modern measurement was Karl Friedrich Gauss. He was born on April 30, 1777, in Brunswick, Germany. At age twenty-four, Gauss published a brilliant work, Disquisitiones Arithmeticae, in which he established basic concepts and methods of number theory. In 1801, Gauss developed the method of least squares in calculating the orbital component of the motion of celestial bodies with high accuracy. Since that time the method of least squares has been the most widely used method in all of science to estimate the impact of measurement error. He was able to prove that a bell-shaped, normally distributed error curve is a basic assumption of statistical probability analysis (Gauss-Markov theorem).

Among all science and social science disciplines, there are three broad measurement theories (Michell 1986, 1990). The first and most commonly used is the classical theory of measurement. Measurement is defined by the magnitudes of the quantity and expressed as real numbers. An object’s quantitative properties are estimated in relation to one another, and ratios of quantities can be determined by the unit of measurement. The classical concept of measurement can be traced back to early theorists and mathematicians, including Isaac Newton and Euclid. The classical approach assumes that the underlying reality exists, but only quantitative attributes are measurable, and the meaningfulness of scientific theories can, and only can, be supported by the empirical relationships of various measurements.

The second theory, the representational approach, defines measurement as “the correlation of numbers and entities that are not numbers” (Nagel [1932] 1960, p. 121). For example, IQ scores can be used to measure intelligence, and the Likert scale measures personal attitudes based on a set of statements. The representational approach assumes that a reality exists and can be measured, and the goal of science is to understand this reality. However, the representational approach does not insist that only quantitative properties are measurable. Instead, measurements can be used to reflect differences at multiple levels.

Unlike the classical and representational approaches, the third approach, called the operational approach, avoids the assumption of objective reality. Instead, it emphasizes only the precisely specified operational process, such as the measurement of reliability and validity. The main concern of scientific theories is only the relationships indicated by the measurements rather than the distance between the reality and measures.

According to the different properties and relationships of the numbers, there are four different levels of measurement: nominal, ordinal, interval, and ratio. In nominal (also called categorical) measurement, names or symbols are assigned to objects, and this assignment is determined by the similarity of the to-be-measured values or attributes. The categories of assignment in most situations are defined arbitrarily, for instance, numbers assigned to individual marital status: single = 1, married = 2, separated = 3, divorced = 4, and so on, or to religious preference: Christian = 1, Jewish = 2, Muslim = 3, Buddhist = 4, and so on.

In ordinal measurement, the number assigned to the objects based on their attributes reflects an order relation among them. Examples include grades for academic performance (A, B, C …), the results of sporting events and the awarding of gold, silver, and bronze medals, and many measurements in psychology and other social science disciplines.

Interval measurements have all the features of ordinal measurements, but in addition the difference between the numbers reflects the equivalent interval of the attributes being measured. This property makes comparison among different measures of an attribute or characteristic meaningful and operations such as addition and subtraction possible. Temperature in Fahrenheit or Celsius degrees, calendar dates, and standardized intelligence tests (IQ) are a few examples of interval measurements.

In ratio measurement, objects are assigned numbers that have all the features of interval measurements, but in addition there are meaningful ratios between the numbers. In other words, the zero value is a meaningful point on the measurement scale, and operations of multiplication and division are therefore also meaningful. Examples include income in dollars, length or distance in meters or feet, age, and duration in seconds or hours.

Because measurement can be arbitrarily defined by the government, researchers, or cultural norms, it is socially constructed. The social construction of measurement is frequently encountered in social science disciplines. For instance, the U.S. Census Bureau has redefined the measure of race several times. Before the 1980 census, census forms contained questions about racial categories,
but the categories included only white, black, American Indian, and specified Asian categories. The census was based on the Office of Management and Budget’s (OMB) 1977 Statistical Policy Directive Number 15, Race and Ethnic Standards for Federal Statistics and Administrative Reporting, defining four mutually exclusive single-race categories: white, black, American Indian or Alaska Native, and Asian or Pacific Islander. In addition, the standards also provided two ethnicity categories: Hispanic origin and Not of Hispanic origin. The 1980 and 1990 censuses were collected according to these standards.

By 1997, OMB modified the race/ethnicity measurement again by splitting the Asian or Pacific Islander category into two groups, creating five race categories: white, African American, American Indian or Alaska Native, Asian, and Native Hawaiian or Other Pacific Islander. In addition, the 2000 census allowed people to identify themselves as belonging to two or more races. It also created six single races and fifty-seven multiple race categories. The ethnicity measure for Hispanic doubled the total number of the race/ethnicity categories to 126. However, such an extensive number of measures causes even more problems. Many Hispanics consider their ethnic origin as a racial category and therefore choose “some other race” on the census form, leading to over 40 percent of the Texas population reported as “some other race.” The misconstruction of the categories of race and ethnicity in the U.S. census illustrates the fluid and subjective nature of measurement.

MEASUREMENT ERROR

Measurement error refers to a circumstance in which the true empirical value of a variable cannot be observed or measured precisely. The error is thus the difference between the actual value of that variable and what can be observed or measured. For instance, household consumption/expenditures over some interval are often of great empirical interest (in many applications because of the theoretical role they play under the forward-looking theories of consumption). These are usually observed or measured via household surveys in which respondents are asked to catalog their consumption/expenditures over some recall window. However, these respondents often cannot recall precisely how much they spent on the various items over that window. Their reported consumption/expenditures are thus unlikely to reflect precisely what they or their households actually spent over the recall interval.

Unfortunately measurement error is not without consequence in many empirical applications. Perhaps the most widely recognized difficulty associated with measurement error is bias to estimates of regression parameters. Consider the following regression model:

\[ y = \beta_0 + \beta_1 \cdot x + \varepsilon \]

If \( y \) and \( x \) are observed precisely (and assuming no other complications), \( \beta_0 \) and \( \beta_1 \) can be estimated via straightforward linear regression techniques. Suppose, however, that we actually observe \( x^* \), which is \( x \) plus some randomly distributed error \( \nu \):

\[ x^* = x + \nu \]

In terms of observed variables, our regression model now becomes

\[ y = \beta_0 + \beta_1 \cdot (x^* - \nu) + \varepsilon \]

\[ = \beta_0 + \beta_1 \cdot x^* + \varepsilon - \beta_1 \cdot \nu \]

\[ = \beta_0 + \beta_1 \cdot x^* + \zeta \]

where \( \zeta = \varepsilon - \beta_1 \cdot \nu \). From this setup, a problem should be immediately apparent. Because \( x^* = x + \nu \) and \( \zeta = \varepsilon - \beta_1 \cdot \nu \), \( x^* \) is correlated with the error term \( \zeta \), violating a central assumption of linear regression (that is, independence between regressors and the regression error) required to recover consistent, unbiased estimates of regression parameters. If one were to regress \( y \) on what we can observe (that is, \( x^* \)), the probability limit of the estimate of \( \beta_1 \), \( \hat{\beta}_1 \), would be

\[ \lim_{n \to \infty} \hat{\beta}_1 = \beta_1 \]

Using \( x^* \) thus does not yield a consistent estimate of \( \beta_1 \):

\[ \lim_{n \to \infty} \hat{\beta}_1 = | \beta_1 | \]

If both \( \nu \) and \( \varepsilon \) are normally distributed or if the conditional expectation from the regression model is linear, then this holds even in small samples as an expectation (Hausman 2001):

\[ E(\hat{\beta}_1) = \left( \frac{\sigma_\varepsilon^2}{\sigma_\varepsilon^2 + \sigma_\nu^2} \right) \cdot \beta_1 \]
Measurement Error

This is generally referred to as attenuation bias. While measurement error to right-hand side explanatory variables will also result in biased and inconsistent estimates in a multiple regression framework, the direction of bias is less clear and will depend on the correlations between the measurement errors of the various regressors. Similarly, biased and inconsistent estimates will obtain when the measurement error \( v \) is correlated with \( \varepsilon \) or \( x \), although once again the sign of the bias will no longer be clear a priori.

Measurement error in left-hand side, dependent variables has a different consequence. To cleanly separate issues, imagine that \( x \) can now be observed perfectly but that we cannot observe the dependent variable \( y \) precisely, but only with a degree of error, as follows:

\[
y^* = y + \nu
\]

Here \( y^* \) is the observed variable. Thus we cannot observe \( y \) directly because of some measurement error \( \nu \). Returning to our regression framework, we have

\[
y = \beta_0 + \beta_1 \cdot x + \varepsilon
\]

which, in terms of observed variables, yields

\[
y^* - \nu = \beta_0 + \beta_1 \cdot x + \varepsilon
\]

or

\[
y^* = \beta_0 + \beta_1 \cdot x + \zeta
\]

where \( \zeta = \varepsilon + \nu \). Since \( x \) is still uncorrelated with the new regression error \( \zeta \), straightforward linear regression of \( y^* \) on \( x \) will still yield unbiased and consistent estimates of the regression parameters \( \beta_0 \) and \( \beta_1 \). However, the variance of \( \zeta \) will in general exceed that of \( \varepsilon \), implying more uncertain estimates (and hence higher standard errors and lower t-statistics for those parameters).

Because it is likely a ubiquitous condition (particularly with many variables typically found in microlevel data, often based on interviews at the household, firm, or individual level), many econometric remedies for measurement error have been proposed. Here we focus on the case of measurement errors in right-hand side explanatory variables \( x \) because it is errors in these that will actually lead to biased and inconsistent (as opposed to merely inefficient) estimates. While a variety of practical solutions has been proposed, in practice one has become particularly popular: instrumental variables.

In some sense the instrumental variables approach is rooted in part in the contributions of Vincent Geraci (1976, 1977), who explored identification and estimation of systems of simultaneous equations with generalized measurement error. Geraci established the necessary conditions for identification and efficient estimation under such circumstances. Of particular importance, his work stressed the need for prior restrictions sufficiently numerous to compensate for the additional parameters introduced by the measurement error.

Despite the rather elaborate work in the context of systems of equations by Geraci and others, in practice most instrumental variables estimation to surmount measurement error is carried out in a simple, two-stage setting. Once again, to isolate issues, let us assume that \( y \) is observed without error but that \( x \) is; specifically, assume that we actually observe \( x^* \), where

\[
x^* = x + \nu.
\]

To implement the instrumental variables remedy for this sort of measurement error, one must have some variable \( z \) (an instrument) that is correlated with the true value \( x \) and not the measurement error \( \nu \). Furthermore \( z \) must be correlated with \( y \) only through its correlation with \( x \). (Following standard results for instrumental variables estimation, \( z \) can be correlated with other observed determinants of \( y \); what it cannot be correlated with is the regression error \( \zeta = \varepsilon - \beta_1 \cdot x \).) Once such an instrument has been identified, the standard two-stage least squares procedure can be adopted: Regress \( x^* \) on \( z \), use the fitted model to predict \( x^* \), and finally, regress \( y \) on the predicted \( x^* \). For example, the case of mismeasured household consumption is often addressed through instruments such as household income (often measured in a separate survey module), local prices (which influence consumption, given income), and the like. What is required is a variable correlated with the true measure and not the error. All the concerns regarding the predictive power of instruments (see, for example, Staiger and Stock 1997) apply.

The result that mismeasured explanatory variables leads to biased and inconsistent estimates generalizes to nonlinear regression and limited-dependent variable models (such as logit and probit), although the instrumental variables solution discussed above is no longer effective. See Jerry Hausman (2001) for further discussion of the case of nonlinear regression and Douglas Rivers and Quang Vuong (1988) for solutions in the case of limited dependent variable models. Interestingly measurement error in dependent variables can lead to biased and inconsistent estimates of model parameters in limited dependent variable models. See Hausman (2001) for further discussion.

MECCA

Makkah al-Mukarramah, or “Mecca the blessed,” as it is called by the government of Saudi Arabia, is the holiest city in Islam. Its unique status derives from its links to the rise of monotheism and the triumph of Islam in Arabia, and its role as a pilgrimage destination for all Muslims.

The pilgrimage to Mecca (hajj)—once in one’s lifetime—is a religious duty for Muslims who can afford it. Pilgrimages to the vicinity predate the founding of Islam (there were evidently pre-Islamic pilgrimages to nearby Arafat and Mina, and the Kaaba was a religious site before it became a focus of worship for Muslims), but the Islamic Mecca hajj is more than 1,300 years old. Muhammad himself completed the pilgrimage in year 10 of the Muslim calendar (632 CE). In modern times, several million Muslims converge on Mecca each year during the last month of the Muslim calendar (Dhu al-Hijjah, literally “Lord of the Pilgrimage”) to perform the necessary rituals, demonstrate and renew their faith, and seek forgiveness for sins. This huge annual gathering of believers from every continent is unique among contemporary religions. Located about 80 kilometers inland from the Red Sea in a desert valley, Mecca could be reached by pilgrims only after extraordinary travels and hardships before the rise of modern transportation in the twentieth century, but now it is serviced by an international airport at nearby Jeddah.

The experience of the pilgrimage combines obedience to prescribed rites, some unavoidable discomfort or even suffering, and, frequently, the exhilaration of religious renewal. As with all major historical pilgrimages, commerce and services have always flourished within and around the hajj. In the contemporary world the hajj also strengthens the sense among Muslims of a worldwide community of believers. The hajj is a leveler: men and women wear the same simple forms of clothing for the rituals (for men, two white cloths wrapped around the body; for women, a simple dress with a head covering). Differences of wealth and status are temporarily put aside as the worshippers submerge themselves in a sea of believers who are—as pilgrims—equal before God. In addition to wearing these simple white clothes, pilgrims must also refrain from anger, disputes, and sexual relations so that they may focus on obedience and devotion to God.

The specific rituals of the hajj cannot be understood without reference to ancient traditions about Ibrahim (Abraham), his wife Hagar, and his son Isma’il (Ishmael), the supposed progenitors of the peoples of Arabia. Some of the rituals reenact the struggles of Hagar and Isma’il to survive in the desert: for example, pilgrims walk and run seven times between the sites of two ancient hills near Mecca, as Hagar did to seek water for her son. The rituals also include stoning a pillar representing the devil, to commemorate Ibrahim’s attempts to fulfill what he believed to be his mission to sacrifice his son. This sacrifice proved to be unnecessary, and Ibrahim was allowed to substitute the sacrifice of an animal. Subsequently, Ibrahim and Isma’il established a holy shrine in the desert that became the cubical structure known as the Kaaba, in Mecca. Although that shrine incorporated icons used for polytheistic worship in pre-Islamic times, these elements were removed after the conquest of Mecca by the Muslim army, led by Muhammad, in 630 CE.

Some elements of the hajj have been modernized. For example, the sacrifice of animals by small groups of worshippers in the traditional hajj (for piety and the sustenance of believers, as the Qur’an asserts, not as offerings sent to God) has been replaced by a sanitized industrial slaughter, after which the meat is packed and shipped to developing Muslim countries overseas. However, the hajj remains an extraordinary demonstration of adherence to ritual traditions as worshippers reenact and remember the struggles and piety of the founders of an ancient and still vibrant monotheism.

MECHANISM DESIGN

Mechanism design deals with the problem of how to design a “mechanism” or a game that has an equilibrium whose outcome maximizes some objective function, such as the maximization of social welfare, subject to certain constraints that depend on the specific problem.

Mechanism design begins with the assumption that each one of the agents for whom the mechanism is designed has access to a different piece of private information, and that elicitation of this information is important for achieving the desired objective. Mechanism design is thus all about incentives: about how to provide the agents with incentives to reveal their private information, and to act in accordance with the designer’s objectives. Accordingly, the most important constraint in mechanism design is called “incentive compatibility,” or IC. The IC constraint obliges the designer to take into account the fact that the agents will try to manipulate the mechanism to their advantage. For example, in one famous mechanism design problem the challenge is how to design an auction that maximizes the expected revenue to the seller under the assumption that the willingness of the potential buyers’ to pay for the auctioned object is their private information.

The roots of the question of how to collect decentralized information for the purpose of allocating resources can be found in economists’ early debates regarding the feasibility of a centralized socialist economy. These early discussions emphasized the complexity of the systems involved, but it soon became evident that any system for making decisions over the allocation of resources might be open to manipulation. One of the first to recognize the importance of incentives in this context was Leonid Hurwicz (b. 1917), who coined the term incentive compatibility in 1959.

Mechanism design was established as a field of study in the early 1970s as a result of Hurwicz’s work on the possibility of attaining efficient outcomes in dominant strategy equilibria in “economic environments”; the investigation by James Mirrlees into optimal income taxation schemes; and the studies by Edward H. Clarke and Theodore Groves of efficient dominant strategy mechanisms for the provision of public goods, which are known as “Vickrey-Clarke-Groves,” or VCG, mechanisms (William Vickrey studied such mechanisms in the 1960s in the context of his work on auctions). In the late 1970s Kenneth Arrow and Claude d’Aspremont and Louis-André Gerard-Varet showed that it was possible to obtain incentive compatible, efficient, and budget-balanced mechanisms. However, in 1983, in their research into optimal mechanisms for bilateral trade, Roger Myerson and Mark Satterthwaite showed that these earlier possibility results might break down if the agents were permitted to refrain from participation in the mechanism if it does not give them an expected utility that is larger than their reservation utility. In 1982 Myerson published a paper on optimal auctions that to this day serves as the model for implementing mechanism design. The literature on mechanism design continued to expand, and presently encompasses price discrimination, regulation, public-good provision, taxation, auction design, procurement, the organization of markets and trade, and more.

Mechanism design has not had the effect on policy anticipated by its early practitioners. This is probably because many of its main results are not robust against changes in the details of the underlying environment (as argued by Robert Wilson in the so-called Wilson Critique). It still remains to be seen whether the current work on “robust mechanism design” would make the theory more practicable.

MEDIA

In conversation, the term the media generally refers to communication media or mass media, which are available to a plurality of recipients and are conceived collectively, as a single, all-encompassing and pervasive entity. Originally meaning an intermediary or a middle quantity, the word medium has been in use since the sixteenth century. By the 1700s, the term was used to refer to currency and a medium of exchange. In the nineteenth century, medium tended to indicate a material used in creative expression and a “channel of mass communication.” Since the early twentieth century, medium has referred to “any physical material … used for recording or reproducing data, images, or sound” (Oxford English Dictionary Online). The term media carries different meanings in various fields. In the field of natural science, a medium is a substrate, whereas in the arts it is a material with distinctive physical properties. In media studies and other social sciences, media typically refer to “the means of communication” (print or broadcast media) or “certain technical forms by which these means are actualized” (books, newspapers, television, radio, film, and now the Internet and video games) (O’Sullivan et al. 1994, p. 176).

Each medium—from the newspaper to the telephone to the personal digital assistant—has its own formal properties and preferred content, arises from distinctive political, economic, and cultural matrices, and holds the potential to influence individuals and society in varying ways. There are obvious limitations to regarding media only as technical devices for delivering content to receivers or audiences. The functions and impact of the media can be sufficiently understood only if broader social dimensions of communication are taken into account.

MEDIA AND SOCIETY

Today there is widespread recognition that the media have had significant impacts—both beneficial and deleterious—on individuals and societies through all stages of their development, playing key roles in socialization and education. They have been variously charged with watering down political debate while also opening up new political forums, and with debasing popular discourse while also facilitating more democratic access to educational resources.

Throughout the history of communication, each era’s predominant media have reflected the shape and character of the civilizations that created and made of use them. Harold Innis (1894–1952), a Canadian economic historian, regards media as “staples” allowing for the creation of monopolies of knowledge, and he explores the impact of the media on the spatial and temporal organization of power. Durable, or what he calls “time-biased,” media, like stone and clay tablets, make a society or empire tend toward longevity (e.g., the Egyptian civilization), whereas light, portable, “space-biased” media, like papyrus, allow for territorial expansion, as with the Roman Empire. In the latter part of the fourteenth century, block printing techniques, first developed in East Asia, reached Europe, where, by the 1450s, metal printing was developed by Johannes Gutenberg. Printing technology revolutionized religion and education in Europe by bringing the word, printed in vernacular languages, to the public. Print culture has been essential to the development of such aspects of Western modernity as rational individualism, scientific knowledge, the nation-state, and capitalism. The emergence of radio broadcasting in the 1920s ushered in a new era in the development of electronic communication media. The ability of radio to reach, simultaneously, unprecedented numbers of people was soon exploited by totalitarian regimes. The rise of film necessitated the creation of a massive industry and new communal exhibition spaces, forged new relationships between media makers and politicians (e.g., the Committee on Public Information), and provided a new form for addressing timely social issues. In the mid-twentieth century, television, through both its form and content, reinforced post-war consumerism and a turn inward, to the private suburban home and the nuclear family.

THEORIES OF MEDIA

Not until recently have the media received sufficient critical attention in academic fields. Classical thinkers such as Karl Marx (1818–1883), Max Weber (1864–1920), and Emile Durkheim (1858–1917) neglected the role of the media in the development of modern societies. With industrialization, urbanization, and modernization, the growth of the media accelerated, as did scholars’ interest in it. Communication studies programs began appearing in Western universities in the early twentieth century. These early programs tended to focus on the use of media in public address—during the war years, for propaganda—and on media’s effects on its audiences. A critical analysis of the medium itself—and not on the process of communication or rhetoric—is a relatively new development, one that distinguishes media studies from communication studies. The various approaches to the media can be divided into three general categories, in accordance with their particular focus—though it should be noted that these are not mutually exclusive and are commonly applied in combination.

Media and Political Economics The political economics approach advanced studies of media in the mid-twentieth century. Walter Lippmann (1889–1974) studied the formation of public opinion through propaganda, while Harold Lasswell (1902–1978) conducted empirical analy-
ses of communication, commonly through content analyses of propaganda in the two World Wars. Yet this early work tended to focus on the effects of a medium’s message on the audiences and paid little attention to the nature of the medium itself. Through his investigation of the transformation of the public sphere, Jürgen Habermas (b. 1929) critically examined the political role of the print media—such as the periodical press—during the transition from absolutism to liberal democracy in the late eighteenth and early nineteenth centuries. The conventional Marxist theory of the media is also one of the main schools of the political economic approach. More recent political economic media scholarship, including the work of Noam Chomsky (b. 1928) and Robert McChesney (b. 1952), focuses on ownership of media organization and argues that the consolidation of ownership in the hands of a few large media corporations limits the variety of ideas presented to the public. Theorists of this type also emphasize the institutional nature of media, focusing on the labor of media production (e.g., work in the newsroom or on the film set).

**Media and Technology** The technological approach focuses attention on the material substance of the media. This approach tends to examine the technological attributes, the form, of the medium, and the impact that those material qualities have on individual and social development. The famous dictum of Marshall McLuhan (1911–1980), “The Medium is the Message,” illustrates the importance of the technical form of media irrespective of their content. Understanding media as extensions of the human body, McLuhan argued that media technologies encourage distinctive modes of thought and perception, which has profound social consequences. Print, for instance, encourages rational, linear thinking, and portable books, which can be read in private, tend to promote atomization. He also devised the concepts of “hot” and “cool” media to describe how particular media forms encourage more or less participation in the communication process.

**Media and Culture** The cultural approach to media tends to examine the interplay between cultural production, identity politics, media representation, and reception, often in quotidian settings and situation. The theorists of the Frankfurt school made significant contributions to the early development of cultural analysis of the media in the 1930s and 1940s. Max Horkheimer (1895–1973) and Theodor W. Adorno (1903–1969) critically investigated the ideological function of communication media as a tool of social domination. According to them, the culture industry, a central characteristic of a new configuration of capitalist modernity, ultimately induced compliance with dominant social relations by utilizing mass communica-

**NEW MEDIA AND POSTMODERNISM**

Electronic and digital media have indeed made their mark on contemporary societies around the globe, introducing new challenges and opportunities. Yet long-lived concerns, including the independence of media from government and corporate control, are extant not only in the postindustrial world, but particularly in developing nations. The role of the media, from the local to the international level, in contemporary political conflicts, from terrorism to political coups, has garnered much attention inside and outside the academy. Meanwhile, video games, often charged with promoting violence and encouraging sedentary lifestyles, are championed by some designers and educators as a revolutionary new tool for hands-on learning. Video cameras, when used as surveillance media, and Internet spyware have also raised political and ethical questions about the uses to which technologies are put: to protect children from potential sexual predators in online chat rooms, to monitor employees’ business-related correspondence, or to track people traffic in urban public places. Personal media technologies such as cellular phones, digital cameras, and MP3 players—many of which have come equipped with global positioning technology—shape users’ conceptions of time and space, changing the way people schedule their daily activities, interact with friends and family, and navigate through space. These new media are influencing the way people learn, create personal identities and social networks, and engage in politics, and the way governments and economies evolve in response to global flows of capital and culture. Jean Baudrillard (1929–2007), a French philosopher, sees
the emergence of cyberspace and new media technologies as creating what he calls simulation and hyperreality. In the age of postmodern society, he argues, the new media-saturated culture becomes predominant over the “real” world, replacing conventional social relations grounded in political economics.

Media—regarded either as a collective, encompassing, mass entity or as individual technologies with distinctive forms and unique political, economic, and cultural characteristics—interact with individuals and societies in ways that have attracted attention both within popular culture and across academic disciplines. And in what is regarded as an increasingly mediated world, their influence will undoubtedly continue to be subjected to scholarly examination and critique.

MEDICAID

The U.S. Medicaid program was enacted in 1965 as Title XIX of the Social Security Act. It is a federal-state program of health-care coverage for some low-income Americans, administered at the federal level by the Centers for Medicare and Medicaid Services. There are distinct Medicaid programs in every state, the District of Columbia, and the U.S. territories, but every program operates within guidelines set at the federal level. Medicaid is financed through federal and state general revenue funds using a formula (based on a state’s per capita income) whereby federal dollars are matched to state dollars at a rate of between 50 and 77 percent. In fiscal year 2004, Medicaid served approximately fifty-two million recipients at a cost of $288 billion.

Medicaid is a highly complex program, in part because there is considerable variation among states. Federal law requires states to cover some populations, referred to as categorically needy, and some services, referred to as mandatory. States may also cover medically needy and special populations and optional services and still receive federal matching funds. The major categorically needy groups are pregnant women and children.
under age six with family income at or below 133 percent of the federal poverty level (FPL); children ages six to nineteen with family income up to 100 percent of the FPL; and aged or disabled people who meet the income eligibility standards for the Supplemental Security Income program. Although there are many more recipients in the first two categories, the largest share of Medicaid dollars is spent on behalf of the third. Aged and disabled Medicaid recipients may also be eligible for Medicare, in which case Medicaid covers what Medicare does not.

Mandatory services for the categorically needy population comprise a comprehensive medical benefit, including inpatient and outpatient hospital, physician, prenatal, and postpartum care, as well as laboratory and x-ray, home-health, and nursing-facility services. Because Medicaid is a means-tested program vying with other state programs for general revenue funds, however, Medicaid reimbursement rates are typically substantially lower than those paid by Medicare and private insurers. Consequently, many Medicaid recipients have difficulty finding providers who will treat them for what the program will pay. Some states have addressed the access problem by requiring that Medicaid enroll recipients in managed-care organizations that contract to serve the program population in return for a yearly per capita payment. Managed care is also viewed as a cost-containment strategy.

Medicaid pays for almost half of all nursing-home care, compared with approximately 12 percent by Medicare and 8 percent by private insurers. Although Medicaid coverage is limited to low-income elders, program rules allow residents to qualify for nursing-home benefits by “spending down” their resources first and then turning to the program for assistance. Because Medicare covers only short-term and medically involved nursing-home stays and because private long-term care insurance is costly and time-limited, even middle-class elderly seek Medicaid benefits in a nursing home. In recent years, states have received federal waivers of some program requirements in order to provide comprehensive long-term care in recipients’ homes.

MEDICARE

Medicare is the name given to public health insurance programs in Canada, Australia, and the United States. In Canada and Australia, the program covers the vast majority of health services for all citizens. The Canadian provinces administer medicare (with a lowercase m) for their inhabitants, and provincial health plans vary in some respects, but in both Canada and Australia, health-care coverage is universal and financed primarily through general tax revenues.

In the United States, Medicare is a public program that provides health insurance for people who are age sixty-five or older, considered disabled by the Social Security Administration (after a two-year wait), or diagnosed with end-stage renal disease. Medicare was enacted in 1965 as Title XVIII of the Social Security Act. In 2005, 42.5 million Medicare beneficiaries were covered at a cost of $330 billion. Despite its primarily elderly clientele, Medicare does not pay for long-term care, except for brief, medically involved stays in a skilled nursing facility.

Medicare is organized into parts A through D, each of which corresponds to a different service type with a different financing scheme. Part A is a program of inpatient hospital insurance available to all Medicare beneficiaries; there is no premium, although beneficiaries are required to pay deductibles and co-payments when they use covered services. Part A is financed through a payroll tax of 2.9 percent, paid half by employers and half by employees. Part B provides coverage for outpatient services, including physician visits, therapies, and laboratory tests. Enrollment is voluntary, and beneficiaries pay a monthly premium for coverage and deductibles and co-payments at the point of service. Part B is financed through premiums and general tax revenues. Part C concerns itself with managed care plans. Part D, passed in 2003, represents the largest expansion of Medicare benefits since 1965; as of January 1, 2006, it covers some of the cost of prescription drugs for beneficiaries who enroll. In a departure from earlier Medicare policy, enrollees receive Part D benefits through private insurance plans that offer coverage for different drugs (within limits set by the government) at different premium amounts. Like Part B, Part D is financed through premiums and general revenue funds. Medicare beneficiaries may also purchase private supple-
mentary, or Medigap, insurance policies to cover deductibles, co-payments, and uncovered services.

Medicare is administered at the federal level by the Centers for Medicare and Medicaid Services. The Medicare program's passage followed a decades-long attempt to enact national health insurance for all Americans. Medicare proponents hoped and expected that the program would be a first step toward that end; as of 2007, Medicare for all remained just one of many proposals for health-care reform.

Among other strengths, Medicare has substantially lower administrative costs than private insurers and has instituted innovative payment systems in the form of diagnosis related groups (DRGs) for hospitals and the resource-based relative value scale (RBRVS) for physicians. Under DRGs, hospitals are paid on a prospective basis to encourage efficiency. The RBRVS makes it possible to redress payment imbalances between generalist and specialist physicians.

MEDICINE
In its broadest sense, medicine denotes ideas relating to diagnoses, causes, and cures of illness, as well as the practice of restoring and maintaining health, and the substances used in the treatment of disease. Medicine is both a domain of knowledge and the application of that knowledge. Medical ideas and practices as well as the social institutions relating to health compose a medical system. Medical systems include ways of classifying disease (cancer, a cold, soul loss, and spirit possession), health specialists (doctors, herbalists, and shamans), and therapies to end illness (pharmaceuticals, meditation, acupuncture, and divination).

Western medicine, or biomedicine, is currently the most widespread medical system, but thousands of others exist throughout the world. Although each tradition is different, diagnosis and treatment often consist of both magical and herbal components. For instance, many societies believe that ill health can be attributed to supernatural forces, which can be meted out by spirits, gods, ancestors, sorcerers, or witches. These forces are capable of causing both the body and the soul to become ill. To combat disease, patients and healers can also invoke magical substances, rituals, or supernatural beings. Another common method of healing is herbalism, using plants to treat illness. An immense variety of plant species are employed as remedies and include decongestants, pain relievers, and antiseptics. Plants in the Americas have been used to derive important drugs including aspirin, quinine, and novocaine. Although nonbiomedical traditions were once regarded as ineffective and superstitious, they are now acknowledged as providing new sources of medicinal plants as well as information regarding the social lives, environments, and experiences of humans.

Medical ideas and practices both constitute and are constituted by social and cultural beliefs and concerns. Arthur Kleinman notes that medicine is a cultural system "of symbolic meanings anchored in particular arrangements of social institutions and patterns of interpersonal interactions" (1990, p. 24). Illness dialogues, diagnoses, and treatments can express ideas regarding religion, morality, power, politics, identity, economics, and gender. Consequently, social scientists are able to examine medical systems and their components as one method of understanding societal norms, attitudes, and practices. For instance, in The Birth of the Clinic (1973) Michel Foucault examines what he calls the "clinical gaze," to show how medicine is linked to power. In AIDS and Accusation (1992) Paul Farmer explores how AIDS dialogues in the United States and Haiti reflect attitudes of colonialism, capitalism, and poverty. Social science research regarding the conceptions and use of medicine can focus on both local environments and global ones.

HISTORY OF MEDICINE
The purposeful treatment of illness has probably occurred throughout the entire span of human existence. However, without written records, it is impossible to know for certain what the earliest types of medical treatment were. The first written evidence of medical knowledge, including lists of symptoms, diagnoses, and treatments, comes from Mesopotamia and Egypt, dating to more than four thousand years ago. In ancient Mesopotamia 250 vegetable and 120 mineral drugs were documented (Magner 1992, p. 19). But it is ancient Egypt that can claim both the first real physician known by name, Imhotep (c. 2980 BCE), and later, the first formalized medical system, which included medical schools, medical insurance, sick leave, and registered physicians of both sexes. The ancient Mesopotamian and the Egyptian medical systems also
incorporated magical remedies. These were the first of a number of codified medical traditions that developed around the world.

The ancient medical systems of India and China were developed later than those of Mesopotamia and Egypt but they are still practiced today. In India, Ayurveda (the science of life) was intended to maintain health, not simply treat disease. Ayurvedic practitioners believe that health is the result of the balance of three _doshas_ (elemental manifestations in the physical body) that govern body processes. Magner notes that ancient texts list more than one thousand diseases and almost one thousand drugs, and describe advanced surgical procedures including cesarean section, amputation, lithotomy, cauterization, tonsillectomy, and plastic surgery (p. 43). Like Ayurveda, traditional Chinese medicine also views disease as the result of an imbalance in the body, which is composed of _yin_ and _yang_ elements. Doctors often make diagnoses by studying the pulses of patients and were aware that the heart was responsible for circulating blood long before Europeans were. Chinese medicine employs a variety of treatments including more than five thousand medicinal herbs (such as ginseng), acupuncture (inserting needles into the body at specific points), and moxibustion (applying a burning tinder to the skin).

In classical Greece, Hippocrates (460–361 BCE), sometimes called the “Father of Medicine,” wrote that health was the result of a balance between the four humors (basic bodily fluids) of phlegm, yellow bile, black bile, and blood. During the Roman Empire the humoral approach was used by many physicians, including Galen (130–200 CE). His writings were used as important medical texts throughout Rome, the Islamic world, and Europe for centuries. Islamic doctors further embraced and modified the Greek tradition and spread it from Spain to India. The medical writings of the doctor and philosopher Ibn Sina (Avicenna, 980–1037) became standard texts throughout the Arab conquests and Medieval Europe. In Europe it was not until the scientific revolution of the sixteenth and seventeenth centuries that the Greco-Islamic tradition was fully abandoned.

In 1628 William Harvey (1578–1657) challenged the Galenic tradition when he published what was then an unorthodox idea: that the pumping heart moved a continuous flow of blood through the body. Almost one hundred years later the Turkish and African practice of purposefully exposing individuals to mild strains of smallpox to achieve inoculation caught the attention of Europeans and Americans, leading to the development of the first vaccine. Nonetheless, it was not until the nineteenth century that advances in chemistry and medical technology led to the discovery of microbial sources of disease and their cures. This allowed researchers to isolate, treat, and create vaccines for diseases such as tuberculosis, tetanus, cholera, and rabies. The introduction of general anesthesia (1840s) and antisepsis (1870s) precipitated the growth of surgery and hospitals, but it was not until the twentieth century that significant advances were made.

**MEDICINE TODAY**

The product of a specific historic and cultural past, biomedicine is currently used around the globe. The biomedical system includes professional, scientific, educational, legal, financial, and ethical frameworks. Biomedicine can be characterized by a number of features. One is its almost exclusive use of science and technology to fight disease. Unlike many other traditions, biomedicine views disease as caused by only natural factors. Supernatural or magical sources of illness or treatments are absent. Most biomedical treatments involve the use of synthesized pharmaceuticals and some require hospitalization. Furthermore, the physical body, not the soul, is considered to be the only locus of illness. Given its early history, biomedical practitioners often have a tendency to look for and find a single cause of an illness (such as a microbe) and then to treat it with a single cure (such as antibiotics). Deborah Gordon (1988) notes that the scientific approach of biomedicine is not only a way to treat illness; it is also a way of conceptualizing the world.

The focus of biomedicine is illness and not health, which is often defined as the absence of disease. Critics charge that because biomedicine almost exclusively treats the body and disease, it lacks a holistic approach to well-being that engages with the social individual. Patients who feel that biomedicine is not meeting their needs have a number of other therapeutic options from which to choose. In developed counties such as the United States, complementary and alternative medicines are widely used. In 1998 Eisenberg et al. estimated that number of visits to alternative medicine practitioners exceeded the total number of consultations with primary care physicians in the United States. These therapies, which include herbalism, meditation, yoga, massage, acupuncture, aromatherapy, and chiropractic medicine, are used either in conjunction with, or as a substitute for, biomedical treatment. They are often provided by nonlicensed healers and can incorporate religious or non-Western traditions.

Throughout much of the world, the majority of medical consultations are still with traditional healers and not biomedical personnel. Nevertheless, indigenous and local healing traditions are often used in conjunction with biomedicine. For instance, in India and China, Ayurveda and traditional Chinese medicine, respectively, continue to play important roles in the public health care systems alongside biomedicine. Magner notes that in the 1960s acupuncture anesthesia was used in 60 percent of all sur-
geries in China (1992, p. 59). Australian Aboriginal people have the choice of going to a biomedical clinic, using local plants as remedies, or consulting local healers to cure spiritual sickness. In Africa herbalists and diviners, as well as doctors and nurses, are regularly consulted. Throughout our history, humans have employed a variety of techniques to treat illness, and this process continues today.

**MEDICINE, SOCIALIZED**

The *American Heritage Dictionary* (4th ed., 2001) defines socialized medicine as “a system for providing medical and hospital care for all at a nominal cost by means of government regulation.” This leaves room for considerable craftsmanship in the construction of socialist systems. Indeed existing socialized medical systems in, for example, Great Britain, Cuba, Finland, and Switzerland conform to this definition, but are far from monolithic.

Because every aspect of a socialized health care industry is controlled and provided by the government—most doctors, nurses, medics, and administrators are government employees—the system, such as the National Health Service (NHS) in Britain, determines where, when, and how services are provided. Of course citizens may seek care outside the system, in the private sector.

Socialized medical systems are designed to eliminate the insurance industry and marginalize profit while providing health care for all. According to many recent studies, socialized systems outperform free-market profit-driven systems in terms of availability, quality, and cost of care. In addition a report from the Johns Hopkins University Bloomberg School of Public Health stated that the United Kingdom’s socialized medical system outperforms the U.S. system in patient-reported perceptions (Blendon, Schoen, DesRoches, et al. 2003). In other words, the people with direct experiences report greater satisfaction with their health services under a socialized system than they do in a free-market system. These results must be considered along with the fact that the U.S. per capita health care expenditures ($4,887) are nearly triple those in the United Kingdom ($1,992). In the year 2000 the United States spent 44 percent more on health care than Switzerland, the nation with the next highest per capita health care costs. Nevertheless, Americans had fewer physician visits, and hospital stays were shorter compared with those in most other industrialized nations. The study suggests that the difference in spending is caused mostly by higher prices for health care goods and services in the United States.

The British system is probably the most instructive example for Americans to evaluate because of the similarities in economy and government structure between the two nations. According to the NHS Web site, the system “was set up on the 5th July 1948 to provide healthcare for all citizens, based on need, not the ability to pay” (National Health Service 2007). Originally conceived as a response to the massive casualties of World War II (1939–1945), the system survives and continues to evolve in the early twenty-first century. The NHS is funded by taxpayers and managed by the Department of Health, which sets overall policy on health issues. Individual patients are assigned a primary care center (with doctors, dentists, optician, pharmacist, and a walk-in center) managed by a primary care trust (PCT). The NHS explains its system of referrals this way: “If a health problem cannot be sorted out through primary care, or there is an emergency, the next stop is hospital. If you need hospital treatment, a general practitioner will normally arrange it for you” (National Health Service 2007).

The PCTs are responsible for planning secondary care. They look at the health needs of the local community and develop plans to set priorities locally. They then decide which secondary care services to commission to meet people’s needs and work closely with the providers of the secondary care services to agree about delivering those services.

The NHS may be the world’s most sophisticated socialized medical system, but the modern world’s first
such system was established by the former Soviet Union in the 1920s. Whereas the NHS demonstrates that socialized medicine can exist within a capitalist economy, the failures of Soviet medicine demonstrated how corruption within a society can distort any system. China, Cuba, Sweden, and most of Scandinavia have successful and completely socialized health care systems.

Life expectancy and infant mortality rates are two of the best indicators of overall health. Average life expectancy in Great Britain was 77.4 years in 1998; in comparison, life expectancy for the U.S. population reached 76.9 years in 2000. Infant mortality in Finland is below 4 percent; in the United States it is 7 percent. Health services are available to all in Finland, regardless of their financial situations.

Single-payer systems such as Medicare are not socialized medicine. In socialized systems the government owns, operates, and provides every aspect of the health care services. Although it is true that in a single-payer system the government collects and disperses the capital for services rendered, its decision-making responsibilities end there. Even without socialized medicine’s additional powers to limit corporate profits, studies by the U.S. General Accounting Office and the Congressional Budget Office show that single-payer universal health care would save $100 to $200 billion dollars per year while covering ever currently uninsured American and increasing health care benefits to those already insured (U.S. Government Accounting Office 1991; Congressional Budget Office 1993).

Outside of the United States, health care in the twenty-first century is increasingly seen as a basic human right that deserves to be protected and provided at an affordable fee to all citizens of civilized societies. This idea—that medical procedures and health care in general should not be subject to or motivated by market forces—is one that, in the late twentieth century, evolved back into favor only after repeated experiments with the capitalization of health care led to systematic and catastrophic failures, resulting in grotesque profits on the supply side contrasted with the suffering of millions of disenfranchised patients on the demand side of the equation. Socialized medicine is an egalitarian system that addresses these inequities.

MEDICIS, THE

The story of the Medici family is closely associated with four historical developments of great interest to scholars in the social sciences: the history of Florence, Italy, and the Florentine “republic” in particular; the development of humanism and the attendant rise of a new association of humanist scholars and artists; the life story and scholarly career of Niccolò Machiavelli; and the history of the Roman Catholic Church.

The Medici first arrived in Florence around 1200 CE from the Mugello region north of Florence. During the thirteenth century the city of Florence became increasingly famous and prosperous due to its success in the cloth and woolen trade, but also became increasingly divided between those who supported the pope, the Guelphs, and those who supported the German emperor, the Ghibellines. These developments provided the framework for two changes central to an understanding of Florentine history and to the rise of the Medici to power. Success in commerce and trade led to the creation of trade guilds, among which was the guild of bankers (Arte del Cambio), and the division between papal and imperial partisans continued to plague Florence well into the sixteenth century. The Medici made their fortune and achieved their status in the banking business and within the greater guilds of Florence. And, for the most part, the Medici aligned themselves with the interests of the papacy.

The first reference to the Medici in the records of the city is to Ugo de Medici in the year 1280. He was banished from the city for disturbing the peace. Shortly after, in 1293, the city adopted the Ordinances of Justice, which
all but guaranteed that the most important guilds, the *Arti Maggiori*, would govern Florence. Most workers, the *ciompi* (wool combers), were ineligible for membership in these guilds and had no share in city governance. Following a revolt of the *ciompi* and a brief period of shared rule (1378–1381) the trade guilds reasserted control and came to be dominated by the Albizzi family, all in the name of a "republican" form of government. The Medici family, under the leadership of Giovanni di Bicci de Medici (1360–1429), emerged in the late fourteenth century as a challenger to the Albizzi, eventually replacing them as the dominant family in the republic. With the death of Giovanni, his son Cosimo assumed leadership of the family and the city of Florence.

For reasons having to do with excessive wealth and ambition, Cosimo de Medici (1389–1464) was exiled from the city in 1433 along with his younger brother Lorenzo. Largely due to his wealth and influence outside of Florence, however, Cosimo was able to have his exile decree lifted a year later, and upon his return to the city worked with the *signoria*, city executives, to encourage legal and political reforms to strengthen Florence’s independence and free the city from outside threats. Within this more stable political climate, and for the next thirty years, Cosimo began to act as generous patron to the artists and scholars who began to gather in the city.

For his many contributions to Florence, Cosimo de Medici earned the honorific title *Pater patriae*, father of the country. Among his most notable deeds was his patronage of artists and scholars such as Leonardo Bruni (1370–1444), Sandro Botticelli (1445–1510), Poggio Bracciolini (1380–1459), and the famous Platonist Marsilio Ficino (1433–1499). Botticelli’s *Adoration of the Magi* (c. 1476) depicts four generations of the Medici as models for characters at the birth of Jesus. Cosimo also funded the construction and filled the shelves of Europe’s first public library, a library dedicated primarily to housing classical and early Christian manuscripts. Cosimo had two sons, Piero (1416–1469) and Giovanni (1421–1453). Piero suffered throughout his life with a severe case of gout and served as head of the family only briefly (1464–1469). It was Piero’s son Lorenzo, however, who assumed leadership of the family from 1469 and who came to be called *il Magnifico*, the magnificent.

Lorenzo the Magnificent (1449–1492) was only twenty years old when he assumed his duties as both head of the Medici family and shaper of Florentine policy. Following his grandfather Cosimo’s lead, Lorenzo dedicated himself to assisting the rising generation of young artists and scholars. Among the numerous recipients of his patronage were some of the leading creative spirits of the Italian Renaissance, including Michelangelo Buonarroti (1475–1564), Pico della Mirandola (1463–1494), and Leonardo da Vinci (1452–1519). As a young man in his teens, Michelangelo actually lived in the Medici house. He later sculpted the Medici tombs and designed the New Sacristy Chapel of San Lorenzo, which houses them. Lorenzo is also credited with establishing internal stability and external diplomacy to secure Florence’s independence. Soon after Lorenzo’s death, however, Charles VIII entered Florence with his French army, the Medici were banished from Florence, and the Dominican monk Savonarola (1452–1498) became the charismatic leader of the republic for the next three years. It would be another fifteen years before the Medicis returned in 1512. The years 1498 to 1512 are widely regarded as the period of the republic, though Florence had been nominally a republic from the late thirteenth century. The dominant figures during this period of Medici absence were Piero Soderini (1450–1513) and Niccolò Machiavelli (1469–1527).

Machiavelli is most famously associated with the Medici family for his dedication of *Il Principe* (*The Prince*; originally *De Principibus, About Principalities*) to Lorenzo (1492–1519), the Duke of Urbino, grandson of Lorenzo the Magnificent, and father of Catherine de Medici (1519–1589). Catherine, as wife of King Henry II, would serve as queen of France. According to a famous letter of December 10, 1513, Machiavelli originally intended to dedicate the work to Giuliano de Medici (1479–1516), but Giuliano died unexpectedly in 1516. So the dedication went to Giuliano’s nephew instead. In either case, the dedication was intended to curry favor with the Medicis, who were back in control of Florence. Though Machiavelli never returned to a position of authority in Florence under the Medicis, he did go on minor diplomatic missions on their behalf, to Lucca in 1520, and to Carpi in 1521. He was also commissioned by the Medici to write one of his most famous works, the *Istorie fiorentine* (*History of Florence*). It is somewhat ironic that in the last years of Machiavelli’s life, from 1523 to his death in 1527, Florence was for all practical purposes under the rule of Ippolito and Alessandro, the illegitimate sons of Giuliano and Lorenzo de Medici, the two dedicatees of *The Prince*.

The Medici family also played an important role in the history of the Roman Catholic Church. Indeed, Lorenzo the Magnificent’s son, Giovanni, and nephew, Giulio, were elected pope. Giovanni de Medici (1475–1521), brother of Giuliano, for whom Machiavelli originally intended *The Prince*, became Pope Leo X in 1513. He is perhaps best remembered as the pope who excommunicated Martin Luther (1483–1546) in 1521. Giulio, who was a cardinal and close associate during his cousin’s reign as pope (1513–1521), became Pope Clement VII in 1523. Pope Clement VII is the pope who famously refused to grant King Henry VIII (1491–1547) of England a divorce from Catherine of Aragon...
(1485–1536), which prepared the ground for the establishment of the Church of England.

MEDIUM IS THE MESSAGE
“The medium is the message” is one of the most famous—yet controversial—statements in the field of media and communication studies. The Canadian literary scholar and pioneering media analyst Herbert Marshall McLuhan (1911–1981) coined the phrase after hearing the anthropologist Ashley Montagu (1905–1999) deliver a talk on science titled “The Method is the Message.” McLuhan’s expression refers to the significance of the form of communication media irrespective of its content; that is, the communication medium itself has the potential to influence the way a particular medium’s content is perceived and to shape cultures dominated by particular media. This dictum, which is also the title of the first chapter of McLuhan’s provocative book Understanding Media: The Extensions of Man (1964), encapsulates the central foundations of his broader analyses of the profound impact of communication technology on society, culture, and human senses.

Until the mid-1950s McLuhan’s work primarily consisted of literary and cultural criticism that examined new forms of popular culture, with an emphasis on the increasing role of mass media in the emergence of consumerism, as well illustrated in The Mechanical Bride (1951). From the later 1950s on, McLuhan turned more attention to the technological properties of communication and the vast effects of the media on human cognition and sensation. Conventional communication studies, he thought, were preoccupied with analyzing media content, while taking for granted the medium as a mere technical device to deliver the message to the receiver. McLuhan, instead, privileged the medium over the message, or form over content; even content is form. He argued that the content of any medium is not only a message, but also, more importantly, always another medium. For instance, the written word is the content of print and, at the same time, the medium of speech. McLuhan defined medium broadly, regarding many cultural artifacts as media and arguing that their work as “media” extended beyond the mere conveyance of content. The electric light, McLuhan explained, functions as a medium, as it renders possible certain forms of human activities such as night football or brain surgery. These activities themselves are the “content” of the electric light because they cannot exist without it. In his terminology, the medium designates something that “shapes and controls the scale and form of human association and action” (McLuhan 1964, p. 9). As such, McLuhan extended the term media to mean any forms of technology that function to extend and widen the human senses and limbs by abolishing temporal-spatial limitations. For instance, the telephone is the extension of the ear, just as the wheel is the extension of foot and leg, and clothing is that of skin. McLuhan’s approach sees media as including all technologically constructed artifacts such as buildings, roads, planes, automation, and so on.

Drawing on the work of his mentor, the economic historian Harold Innis (1894–1952), who in his work on the “bias of communication” examined the material substance of communication and its impact on the spatial-temporal organization of societies, McLuhan presented the history of communication as a history of the medium, rather than as a history of the message. McLuhan maintained that the major phases of civilization tended to accord with the introduction and rise to popularity of particular modes of communication technology and consequent changes of the human sensorium at a social level. With the rise of the printing press, social life shifted from a traditional society based upon oral communication to a modern, visual typographic culture that, because of its emphasis on literacy and uniformity, made possible the rise of rational individualism and western nationalism. Since then, electronic media pushed culture into an unprecedented, turbulent media revolution—a technocultural society in which communication technology itself has become the central nervous system. It is an age of global communication mediated through radio and TV (and the Internet), which has generated diverse and heterogeneous social relations and brought about the retribalization of the world—the “global village,” as McLuhan famously characterized.
The startling new insight implicated in McLuhan’s statement predated the postmodern turn in media studies, which is typified in the work of Jean Baudrillard (1929–2007). Some critics point out that McLuhan’s technological determinist perspective ignores vital questions related to the functions of various media institutions and the ideological effects of the media on the audience. His erratic and poetic style of writing also makes it difficult to formulate a comprehensive theory of the media and society. Yet, the core aspects of his insight contributed to the development of “medium theory” and “media ecology,” elaborated more systematically by later theorists.

MEIJI RESTORATION

The Meiji Restoration of 1868 marked the beginning of Japan’s revolutionary turn away from medieval and early-modern patterns of development, which had been characterized by samurai domination of virtually every aspect of society. Narrowly conceived, the Restoration amounted to little more than the coup d'état of 1868, which forced the resignation of the last Tokugawa (1600–1868) shogun and elevated Emperor Meiji (Mutsuhito, 1852–1912), then a teenager, to sovereign administrative rule. Viewed expansively, however, the Meiji Restoration was more than a mere regime change: It initiated a revolutionary transformation, achieved during the Meiji period (1868–1912), that was comparable in scope to the mid-sixth-century introduction of Buddhism and Chinese civilization. In the mid-nineteenth century, however, the new model for civilization came from the West. The Meiji Restoration brought about a revolution that led to the westernization of virtually all aspects of national life.

Meiji Japan’s embrace of the West reflected its determination to remake itself so as to acquire the power of, and achieve recognition as an equal to, the Western nation-states that dominated it in the 1850s and 1860s. Indeed, the downfall of the last samurai regime, the Tokugawa, resulted largely from its inability to mediate, without internal upheaval, the imperialistic demands of nations such as the United States, made powerful by the Industrial Revolution and seeking trade and diplomatic exchanges with Japan. Until the 1850s the Tokugawa shoguns, fearing the kind of domination that occurred in the Philippines, had effectively minimized contacts with the West. The only Western power permitted to trade with Japanese merchants were the Dutch, and even they were restricted to the artificial island of Dejima, created in Nagasaki Bay to circumscribe the presence of Dutch traders on Japanese soil. As long as maritime technology depended upon the winds, this approach was relatively successful. With the development of steam-powered vessels carrying heavy cannon, Western nations—Great Britain and the United States in particular—were able to dominate East Asia at will, with little significant opposition.

Through the Dutch, the Tokugawa regime was informed of Britain’s defeat of China in the Opium War (1840–1842) and the resulting Treaty of Nanjing (1842). When Commodore Matthew Perry’s flotilla arrived near Edo (Tokyo) in 1852 demanding treaty relations providing for exchanges between Japan and the United States, the Tokugawa regime realized that it had little choice but to comply, despite the fact that doing so violated its raison d’être: defending the realm against barbarian incursions. The resulting Treaty of Kanagawa (1853), though a sensible accommodation, marked the beginning of the end for the Tokugawa insofar as it became the target of unrelenting critiques from anti-Tokugawa forces. Significant opposition emerged from the “outer” (tōzama) domains of Chōshū and Satsuma, centers of long-standing animosities toward the Tokugawa.

Opposing the regime’s strategy of negotiating with the foreigners rather than fighting them, anti-Tokugawa forces called on the shogunate to do its duty: “Revere the emperor and repel the barbarian” (sonnō jōi). When the Americans returned with demands for fuller diplomatic and trade relations, anti-Tokugawa forces intensified their opposition through terrorist attacks. Radical opposition was strong in Chōshū, which launched two military challenges to the Tokugawa in the 1860s. Although the first round of fighting resulted in defeat for Chōshū, in the second it was joined by forces from Satsuma and Tosa domains. The result was the military defeat of the...
Tokugawa in 1866. Within two years, the last of the Tokugawa shoguns, Yoshinobu (1837–1913), had turned over administrative authority over the realm to Emperor Meiji and his backers.

The new regime, ostensibly led by Emperor Meiji, was dominated by opposition leaders from Chōshū, Satsuma, and Tosa who had played instrumental roles in the military strikes that had forced the Tokugawa into a state of collapse. Though often described as statesmen, they remained in significant respects revolutionary leaders, defining a radically new political course that resulted in the creation of a modern nation-state. Ironically enough, once the pro-imperial forces had forced the collapse of the Tokugawa shogunate, the rebels-turned-statesmen proceeded to throw the gates open to the West in a search for knowledge and power. By the end of Emperor Meiji’s reign in 1912, this assimilation of Western knowledge had resulted in across-the-board achievements that impressed the world.

Socially, the imperial regime abolished the old hereditary social hierarchy that had been decreed by the Tokugawa. Economically, it created the yen, Japan’s first national currency, and the Bank of Japan to regulate economic growth. The development of a modern, centralized economy amounted to a revolutionary transformation of earlier economic relations in which the only equivalent to a national currency had been the rice bushel. At the same time, the imperial state induced an industrial revolution by promoting the development of heavy industries such as mining, shipping, and rail transport. Politically, the new regime, under the leadership of Itō Hirobumi (1841–1909), created a representative, constitutionally defined political system. The Meiji government instituted compulsory elementary education at schools created nationwide and established a Western-style conscript force, developed by Yamagata Aritomo (1838–1922) to replace the now-abolished samurai estate. Modeled after the Prussian military, Meiji forces proved effective in defeating internal rebellions and the armies of much larger nations, as seen in the Sino-Japanese War (1894–1895) and the Russo-Japanese War (1904–1905). With the latter victory, imperial Japan finally received the kind of respect internationally that it had long sought. By the end of the Meiji period, Japan was recognized as the leading military and imperial power among East Asian nations.

Geopolitically, Japan was reconfigured during the Meiji period, first with the move of the imperial capital away from its home for over a millennium, Kyoto, to a new center, Edo, the capital of the Tokugawa shoguns, now renamed Tokyo. In the countryside, imperial prefectures replaced the old daimyō domains. Before the Meiji period had ended, the beginnings of an empire were evident in the acquisition of Taiwan in 1895, following the Sino-Japanese War, and the annexation of Korea in 1910, a consequence of the Russo-Japanese War. Japan became a strategic player in the world of military alliances with the Anglo-Japanese Alliance of 1902, in which both nations pledged to support the other in the event of multinational military aggression.

Though not billed in traditional historiography as a revolutionary movement, the Meiji Restoration entailed nothing less than a wholesale transformation of Japan. If there were flaws in the revolution that flowed from the restoration of imperial rule, they had to do with the extent to which military power was increasingly viewed as an expedient means to national power, prestige, and wealth.

MEIR, GOLDA

1898–1978

Golda Meir was born Golda Mabovitz on May 3, 1898, in Kiev, Russia (now Ukraine). Due to terrible hardship, Golda’s family immigrated in 1906 to Milwaukee, Wisconsin, where Golda graduated from a teachers’ college and worked as a public-school teacher. She joined the Labor Zionist Party in 1915 and married Morris Meyerson in 1917. In 1921 they immigrated to Palestine, where they joined Kibbutz Merhavia. In 1956 she adopted the Hebrew name Meir (“to burn brightly”).

Believing that Jews should make their “Just Society” through their own physical labor, Meir was a prominent socialist Zionist figure in the Histadrut (the Israeli Trade Union Congress) and the Jewish Agency, a Zionist organization founded in 1929 to provide services for Jewish immigration and assimilation into Palestine. Being proficient in English, Meir was sent to the United States in the
1930s on a mission to raise funds for building the state of Israel.

After the establishment of Israel on May 14, 1948, Meir played a central role in domestic politics as well as on the diplomatic front. In the same year, she paid a secret, yet unsuccessful, visit to Jordan to persuade its king, Abdulllah (1882–1951), not to attack Israel. David Ben-Gurion (1886–1973), a leader in the struggle to establish the state of Israel and later the first prime minister of Israel, appointed Meir a member of the Provisional Government and then, in June 1948, ambassador to the Soviet Union. In 1949 she was elected to the first Knesset as a member of Mapai, the Israeli Workers Party. Meir served as minister of labor from 1949 to 1956, a period of high unemployment and social unrest that resulted from mass immigration. She served as foreign minister from 1956 to 1966. While in office, Meir sought to strengthen Israel’s relationship with the United States, create bilateral relationships with Latin American countries, and provide African countries with Israeli know-how in nation building.

Meir took a rigid stance toward the Arabs. She also adopted the so-called open-door immigration policy, which encouraged thousands of people to leave the Soviet Union and other places to settle in Israel and the occupied territories. She believed that Israelis could not return the occupied territories because there was nobody to return them to. In a June 15, 1969, interview with the Sunday Times of London, she said, “There was no such thing as Palestinians … they did not exist,” a statement that Arabs often quote to refer to what they think to be bias. Moreover, she wrote in My Life, her 1975 autobiography, that she did not believe that “the Jews ‘stole’ land from Arabs in Palestine,” since “a lot of good money changed hands, and a lot of Arabs became very rich indeed” (p. 63).

The most critical event during her term was the 1973 Arab-Israeli War, when Egypt and Syria attacked Israeli forces in Sinai and the Golan Heights. Although she won the elections once more in December 1973, and despite the fact that the Agranant Inquiry Commission did not hold her responsible for the war, Meir’s performance was widely criticized for overestimating Israel’s preparedness and underestimating Arab power. Meir resigned in mid-1974 and withdrew from public life. She died in Jerusalem in December 1978.

MELTING POT

Amalgamation of settlers of diverse national origin has long been linked with the idealtic self-image of America as a new type of nation-state. The French-born immigrant J. Hector St. John de Crévecoeur (1735–1813), in Letters from an American Farmer (1782), described America as a
country where “individuals of all nations are melted into a new race of men.” Though the nationalities included in the early expression of the melting pot ideal were largely limited to northwestern Europe, the vision of American national identity as based on cross-ethnic amalgamation eventually came to include nearly all European nationalities. British writer Israel Zangwill’s (1864–1926) early twenty-century play *The Melting Pot* was the first to use the term as a metaphor of assimilation in the American context of mass immigration from Europe. The melting pot ideal was depicted in an illustration featured on the play’s theater program, which shows many strands of people walking past the Statue of Liberty into a huge boiling pot. As an ideology of immigrant assimilation, the melting pot has persisted as an idealistic vision of the inclusive nature of assimilation in America.
